**Polypeptide nucleic sequences exported from  
mycobacteria, vectors comprising same and uses for  
diagnosing and preventing tuberculosis**

5           The subject of the invention is novel recombinant  
screening, cloning and/or expression vectors which  
replicate in mycobacteria. Its subject is also a set of  
sequences encoding exported polypeptides which are detected  
by fusions with alkaline phosphatase and whose expression  
10 is regulated (induced or repressed) or constitutive during  
the ingestion of mycobacteria by macrophages. The invention  
also relates to a polypeptide, called DP428, of about 12 kD  
which corresponds to an exported protein found in  
mycobacteria belonging to the *Mycobacterium tuberculosis*  
15 complex. The invention also relates to a polynucleotide  
comprising a sequence encoding this polypeptide. It also  
relates to the use of the polypeptide or of fragments  
thereof and of the polynucleotides encoding the latter (or  
alternatively the polynucleotides complementary to the  
20 latter) for the production of means for detecting in vitro  
or in vivo the presence of a mycobacterium belonging to the  
*Mycobacterium tuberculosis* complex in a biological sample  
or for the detection of reactions of the host infected with  
these bacterial species. The invention finally relates to  
25 the use of the polypeptide or of fragments thereof as well  
as of the polynucleotides encoding the latter as means  
intended for the preparation of an immunogenic composition  
which is capable of inducing an immune response directed  
against the mycobacteria belonging to the *Mycobacterium*  
30 *tuberculosis* complex, or of a vaccine composition for the  
prevention and/or treatment of infections caused by

OFFICE OF PETITIONS

mycobacteria belonging to said complex, in particular tuberculosis.

The aim of the present invention is also to use these sequences (polypeptide and polynucleotide sequences) as target for the search for novel inhibitors of the growth and multiplication of mycobacteria and of their maintenance in the host, it being possible for these inhibitors to serve as antibiotics.

The genus *Mycobacterium*, which comprises at least 56 different species, includes major human pathogens such as *M. leprae* and *M. tuberculosis*, the agents responsible for leprosy and tuberculosis, which remain serious public health problems worldwide.

Tuberculosis continues to be a public health problem in the world. At present, this disease is the cause of 2 to 3 million deaths in the world and about 8 million new cases are observed each year (Bouvet, 1994). In developed countries, *M. tuberculosis* is the most common cause of mycobacteria infections. In France, about 10,000 new cases appear per year and, among the notifiable diseases, it is tuberculosis which comprises the highest number of cases. Vaccination with BCG (Bacille Calmette-Guérin), an avirulent strain which is derived from *M. bovis* and which is widely used as a vaccine against tuberculosis, is far from being effective in all populations. This efficacy varies from about 80% in western countries such as England, to 0% in India (results of the last vaccination trial in Chingleput., published in 1972 in Indian J. Med. Res.). Furthermore, the appearance of *M. tuberculosis* strains which are resistant to antituberculars and the increased risk in immunosuppressed patients, patients

suffering from AIDS, of developing tuberculosis, make the development of rapid, specific and reliable methods for the diagnosis of tuberculosis and the development of novel vaccines necessary. For example, an epidemiological study  
5 carried out in Florida, and of which the results were published in 1993 in AIDS therapies, showed that 10% of the AIDS patients are affected by tuberculosis at the time of the AIDS diagnosis or 18 months before it. In these patients, tuberculosis appears in 60% of cases in a form  
10 which is disseminated and therefore nondetectable by conventional diagnostic criteria such as pulmonary radiography or the analysis of sputum.

Currently, a certainty on the diagnosis provided by the detection of bacilli which can be cultured in a  
15 sample obtained from a patient is obtained in only less than half of the tuberculosis cases, even in the case of pulmonary tuberculosis. The diagnosis of tuberculosis and of the other related mycobacteria is therefore difficult to carry out for various reasons: mycobacteria are often  
20 present in a small quantity, their generation time is very long (24 h for *M. tuberculosis*) and they are difficult to culture (Bates et al., 1986).

Other techniques can be used in clinical medicine to identify a mycobacterial infection:

25 a) The direct identification of microorganisms under a microscope; this technique is rapid, but does not allow the identification of the mycobacterial species observed and lacks sensitivity (Bates, 1979).

Cultures, when they are positive, have a  
30 specificity approaching 100% and allow the identification of the mycobacterial species isolated; however, as

specified above, the growth of mycobacteria *in vitro* is long (can only be carried out in 3 to 6 weeks of repeated cultures (Bates, 1979; Bates et al., 1986)) and expensive.

b) Serological techniques are found to be useful  
5 under certain conditions, but their use is sometimes limited by their low sensitivity and/or specificity (Daniel et al., 1987).

c) The presence of mycobacteria in a biological sample can also be determined by molecular hybridization  
10 with DNA or RNA using oligonucleotide probes which are specific for the sequences tested for (Kiehn et al., 1987; Roberts et al., 1987; Drake et al., 1987). Several studies have shown the advantage of this technique for the diagnosis of mycobacterial infections. The probes used  
15 consist of DNA, ribosomal RNA or DNA fragments from mycobacteria which are obtained from gene banks. The principle of these techniques is based on the polymorphism of the nucleotide sequences of the fragments used or on the polymorphism of the adjacent regions. In all cases, they  
20 require the use of cultures and are not directly applicable to biological samples.

The low quantity of mycobacteria present in a biological sample and consequently the low quantity of target DNA to be detected in this sample can require the  
25 use of a specific amplification *in vitro* of the target DNA before its detection with the aid of the nucleotide probe and using *in vitro* amplification techniques such as PCR (polymerase chain reaction). The specific amplification of the DNA by the PCR technique can constitute the first stage  
30 of a method for detecting the presence of a mycobacterial DNA in a biological sample, the actual detection of the

amplified DNA being carried out in a second stage with the aid of an oligonucleotide probe capable of specifically hybridizing with the amplified DNA.

A test for the detection of mycobacteria  
5 belonging to the *Mycobacterium tuberculosis* complex, by sandwich hybridization (test using a capture probe and a detection probe) was described by Chevrier et al. in 1993. The *Mycobacterium tuberculosis* complex is a group of mycobacteria which comprises *M. bovis-BCG*, *M. bovis*, *M.*  
10 *tuberculosis*, *M. africanum* and *M. microti*.

A method for the detection of low quantities of mycobacteria, belonging to the tuberculosis complex, by gene amplification and direct hybridization on biological samples has been developed. Said method uses the insertion  
15 sequence IS6110 (European Patent EP 0,490,951 B1). Thierry et al. described in 1990 a sequence which is specific to the *Mycobacterium tuberculosis* complex and which is called IS6110. Some authors have proposed specifically amplifying the DNA obtained from *Mycobacterium* using nucleic primers  
20 in an amplification method, such as the polymerase chain reaction (PCR). Patel et al. described in 1990 the use of several nucleic primers chosen from a sequence known as a probe in the identification of *M. tuberculosis*. However, the length of the fragments obtained using these primers  
25 was different from the expected theoretical length and several fragments of variable size were obtained. Furthermore, the authors observed the absence of hybridization of the amplified products with the plasmid which served to determine the primers. These results  
30 indicate that these primers might not be appropriate in the detection of the presence of *M. tuberculosis* in a

biological sample and confirm the critical nature of the choice of the primers. The same year, J.L. Guesdon and D. Thierry described a method for the detection of *M. tuberculosis*, having a high sensitivity, by amplification  
5 of an *M. tuberculosis* DNA fragment located within the IS6110 sequence (European Patent EP 461,045) with the aid of primers generating amplified DNA fragments of constant length, even when the choice of the primers led to the amplification of long fragments (of the order of 1000 to  
10 1500 bases) where the risk of interruption of the polymerization is high because of the effects of the secondary structure of the sequence. Other primers specific for the IS6110 sequence are described in European Patent No. EP-0,490,951.

15 The inventors have shown (unpublished results) that some clinical isolates of *Mycobacterium tuberculosis* lacked the insertion sequence IS6110 and could therefore not be detected with the aid of oligonucleotides specific for this sequence which could thus lead to false-negative  
20 diagnostic results. These results confirm a similar observation made by Yuen et al. in 1993. The impossibility of detecting these pathogenic strains which are potentially present in a biological sample collected from a patient is thus likely to lead to diagnostic difficulties or even to  
25 diagnostic errors. The availability of several sequences specific for the tubercule bacillus, within which primers appropriate for amplification will be chosen, is important. The DP428 sequence described here may be used.

*M. bovis* and *M. tuberculosis*, the causative  
30 agents of tuberculosis, are facultative intracellular bacteria.

These agents have developed mechanisms to ensure their survival and their replication inside macrophage, one of the cell types which is supposed to eradicate invasion by microorganisms. These agents are capable of modulating the normal development of their phagosome and of preventing them from becoming differentiated into an acidic compartment rich in hydrolase (Clemens, 1979; Clemens et al., 1996; Sturgill-Koszycki et al., 1994 and Xu et al., 1994). However, this modulation is only possible if the bacterium is alive inside the phagosome, suggesting that compounds which are actively synthesized and/or secreted inside the cell are part of this mechanism. Exported proteins are probably involved in this mechanism. Despite major health problems linked to these pathogenic organisms, little is known on their exported and/or secreted proteins. SDS-PAGE analyses of *M. tuberculosis* culture filtrate show at least 30 secreted proteins (Altschul et al., 1990; Nagal et al., 1991 and Young et al., 1992). Some of them have been characterized, their genes cloned and sequenced (Borremans et al., 1989; Wiker et al., 1992 and Yamaguchi et al., 1989). Others, although being immunodominant antigens of major importance for inducing a protective immunity (Anderson et al., 1991 and Orme et al., 1993), have not been completely identified. In addition, it is probable that many exported proteins remain attached to the cell membrane and are consequently not present in the culture supernatants. It has been shown that the proteins located at the outer surface of various pathogenic bacteria, such as the 103 kDa invasin of *Yersinia pseudotuberculosis* (Isberg et al., 1987) or the 80 kDa internalin of *Listeria monocytogenes* (Gaillard et al., 1991

and Dramsi et al., 1997) play an important role in the interactions with the host cells and, consequently, in the pathogenicity as well as in the induction of protective responses. Thus, a protein which is bound to the membrane  
5 would be important for the *M. tuberculosis* infection as well as for the induction of a protective response against this infection. These proteins could certainly be of interest for the preparation of vaccines.

Recently, the adaptation, to mycobacteria, of a  
10 genetic methodology for the identification and the phenotypic selection of export proteins has been described (Lim et al., 1995). This method uses *E. coli* periplasmic alkaline phosphatase (PhoA). A plasmid vector was constructed which allows the fusion of genes between a  
15 truncated *PhoA* gene and genes encoding exported proteins (Manoil et al., 1990).

Using this method, it has been possible to identify an *M. tuberculosis* gene (*erp* (Berthet et al., 1995)) exhibiting homologies with a 28 kDa exported protein  
20 of *M. leprae*, which is a frequent target of humoral responses of the lepromatous form of leprosy. A protein having amino acid motifs which are characteristic of plant desaturase (*des*) has also been characterized by the technique of fusion with PhoA.

25 However, this genetic method for identifying exported proteins does not make it possible to easily evaluate the intracellular expression of the corresponding genes. Such an evaluation is of crucial importance both for selecting good candidate vaccines and for understanding the  
30 interactions between bacteria and their host cells. The induction of the expression of virulence factor through

pathogenic target cell contact has been described. It is the case, for example, for the *Yersinia pseudotuberculosis* Yops virulence factors (Petersson et al., 1996). *Shigella*, upon contact with the target cells, releases the Ipa proteins into the culture medium, and *Salmonella* synthesizes novel surface structures.

Taking into account the preceding text, a great need currently exists for developing novel vaccines against pathogenic microbacteria as well as novel specific, reliable and rapid diagnostic tests. These developments require the designing of even more efficient specific tools which make it possible, on the one hand, to isolate or to obtain sequences of novel specific, in particular immunogenic, polypeptides, and, on the other hand, to better understand the mechanism of the interactions between bacteria and their host cells such as in particular the induction of the expression of virulence factor. This is precisely the object of the present invention.

The inventors have defined and produced, for this purpose, novel vectors allowing the screening, cloning and/or expression of mycobacterial DNA sequences so as to identify, among these sequences, nucleic acids encoding proteins of interest, preferably exported proteins, which may be located on the bacterial membrane, and/or secreted proteins, and to identify among these sequences those which are induced or repressed during infection (intracellular growth).

### Description

The present invention describes the use of the reporter gene *phoA* in mycobacteria. It makes it possible to

identify systems for expression and export in a mycobacterial context. Many genes are only expressed in such a context, which shows the advantage of the present invention. During the cloning of DNA segments of strains of the *M. tuberculosis* complex fused with *phoA* into another mycobacterium such as *M. smegmatis*, the beginning of the gene, its regulatory regions and its regulator will be cloned, which will make it possible to observe a regulation. If this regulation is positive, the cloning of the regulator will constitute an advantage for observing the expression and the export.

In the context of the invention, mycobacterium is understood to mean all the mycobacteria belonging to the various species listed by Wayne L.G. and Kubica G.P. (1980). Family Mycobacteriaceae in Bergey's manual of systematic bacteriology, J.P. Butler Ed. (Baltimore USA: Williams and Wilkins P. 1436-1457).

In some cases, the cloned genes are subjected in their original host to a negative regulation which makes the observation of the expression and of the export difficult in the original host. In this case, the cloning of the gene in the absence of its negative regulator, into a host not containing it, will constitute an advantage.

The invention also relates to novel mycobacterial polypeptides and to novel mycobacterial polynucleotides which may have been isolated by means of the preceding vectors and which are capable of entering into the preparation of compositions for the detection of a microbacterial infection, or for the protection against an infection caused by mycobacteria or for the search for inhibitors as is described above for DP428.

The subject of the invention is therefore a recombinant screening, cloning and/or expression vector, characterized in that it replicates in mycobacteria and in that it contains:

- 5 1) a replicon which is functional in mycobacteria;
- 2) a selectable marker;
- 3) a reporter cassette comprising:
  - a) a multiple cloning site (polylinker),
  - b) optionally a transcription terminator which is
  - 10 active in mycobacteria, upstream of the polylinker,
  - c) a coding nucleotide sequence which is derived from a gene encoding a protein expression, export and/or secretion marker, said nucleotide sequence lacking its initiation codon and its regulatory sequences, and
  - 15 d) a coding nucleotide sequence derived from a gene encoding a marker for the activity of promoters which are contained in the same fragment, said nucleotide sequence lacking its initiation codon. Optionally, the recombinant vector also contains a replicon which is
  - 20 functional in *E. coli*.

Preferably, the export and/or secretion marker is placed in the same orientation as the promoter activity marker.

- Preferably, the recombinant screening vector
- 25 according to the invention comprises, in addition, a transcription terminator placed downstream of the promoter activity marker, which is likely to allow the production of short transcripts which are found to be more stable and which consequently allow a higher level of expression of
  - 30 the products of translation.

The export and/or secretion marker is a nucleotide sequence whose expression, followed by export and/or secretion, depends on the regulatory elements which control its expression.

5               "Sequences or elements for regulating the expression of the production of polypeptides and its location" is understood to mean a transcriptional promoter sequence, a sequence comprising the ribosome-binding site (RBS), the sequences responsible for export and/or  
10 secretion such as the sequence termed signal sequence.

A first advantageous export and/or expression marker is a coding sequence derived from the *phoA* gene. Where appropriate, it is truncated such that the alkaline phosphatase activity is nevertheless capable of being  
15 restored when the truncated coding sequence is placed under the control of a promoter and of appropriate regulatory elements.

Other exposure, export and/or secretion markers may be used. There may be mentioned, by way of examples, a  
20 sequence of the gene for  $\beta$ -agarase, for the nuclease of a staphylococcus or for a  $\beta$ -lactamase.

Among the advantageous markers for the activity of promoters which are contained in the same fragment, a coding sequence derived from the firefly luciferase *luc*  
25 gene, provided with its initiation codon, is preferred.

Other markers for the activity of promoters which are contained in the same fragment may be used. There may be mentioned, by way of examples, a sequence of the gene for GFP (Green Fluorescent Protein).

30               The transcription terminator should be functional in mycobacteria. An advantageous terminator is, in this

regard, the T4 coliphage terminator (tT4). Other appropriate terminators for carrying out the invention may be isolated using the technique presented in the examples, for example by means of an "omega" cassette (Prentki et  
5 al., 1984).

A vector which is particularly preferred for carrying out the invention is a plasmid chosen from the following plasmids which have been deposited at the CNCM (Collection Nationale de Cultures de Microorganismes, 25  
10 rue de Docteur Roux, 75724 Paris cedex 15, France):

a) pJVEDa which was deposited at the CNCM under the No. I-1797, on 12/12/1996,

b) pJVEDb which was deposited at the CNCM under the No. I-1906, on 25 July 1997,

15 c) pJVEDc which was deposited at the CNCM under the No. I-1799, on 12/12/1996.

For the selection or the identification of mycobacterial nucleic acid sequences encoding polypeptides which are capable of being incorporated into immunogenic or  
20 antigenic compositions for the detection of an infection, or which are capable of inducing or repressing a mycobacterial virulence factor, the vector of the invention will comprise, at one of the multiple cloning sites of the polylinker, a nucleotide sequence of a mycobacterium in  
25 which the detection is carried out of the presence of sequences corresponding to exported and/or secreted polypeptides which may be induced or repressed during the infection, or alternatively expressed or produced constitutively, their associated promoter and/or regulatory  
30 sequences which are capable of allowing or promoting the export and/or the secretion of said polypeptides of

interest, or all or part of the genes of interest encoding said polypeptides.

Preferably, this sequence is obtained by physical fragmentation or by enzymatic digestion of the genomic DNA  
5 or of the DNA which is complementary to an RNA of a mycobacterium, preferably *M. tuberculosis* or chosen from *M. africanum*, *M. bovis*, *M. avium* or *M. leprae*.

The vectors of the invention may indeed also be used to determine the presence of sequences of interest,  
10 preferably corresponding to exported and/or secreted proteins, and/or capable of being induced or repressed or produced constitutively during the infection, in particular during phagocytosis by the macrophages, and, according to what was previously disclosed, in mycobacteria such as *M.*  
15 *africanum*, *M. bovis*, *M. avium* or *M. leprae* whose DNA or cDNA will have been treated by physical fragmentation or with defined enzymes.

According to a first embodiment of the invention, the enzymatic digestion of the genomic DNA or of the  
20 complementary DNA is carried out using *M. tuberculosis*.

Preferably, this DNA is digested with an enzyme such as *sau3A*, *BclI* or *BglII*.

Other digestive enzymes such as *ScaI*, *ApaI*, *SacII* or *KpnI* or alternatively nucleases or polymerases can  
25 naturally be used as long as they allow the production of fragments whose ends can be inserted into one of the cloning sites of the polylinker of the vector of the invention.

Where appropriate, the digestions with various  
30 enzymes will be carried out simultaneously.

Recombinant vectors which are preferred for carrying out the invention are chosen from the following recombinant vectors which have been deposited at the CNCM:

- 5 a) p6D7 which was deposited on 28 January 1997 at the CNCM under the No. I-1814,
- b) p5A3 which was deposited on 28 January 1997 at the CNCM under the No. I-1815,
- c) p5F6 which was deposited on 28 January 1997 at the CNCM under the No. I-1816,
- 10 d) p2A29 which was deposited on 28 January 1997 at the CNCM under the No. I-1817,
- e) pDP428 which was deposited on 28 January 1997 at the CNCM under the No. I-1818,
- f) p5B5 which was deposited on 28 January 1997 at the CNCM under the No. I-1819,
- 15 g) p1C7 which was deposited on 28 January 1997 at the CNCM under the No. I-1820,
- h) p2D7 which was deposited on 28 January 1997 at the CNCM under the No. I-1821,
- 20 i) p1B7 which was deposited on 31 January 1997 at the CNCM under the No. I-1843,
- j) pJVED/*M. tuberculosis* which was deposited on 25 July 1997 at the CNCM under the No. I-1907,
- k) pM1C25 which was deposited on 4 August 1998 at the CNCM under the No. I-2062.
- 25

Among those which are most preferred, the recombinant vector pDP428 which was deposited on 28 January 1997 at the CNCM under the No. I-1818, and the vector pM1C25 which was deposited on 4 August 1998 at the CNCM under the No. I-2062 are preferred.

30

The subject of the invention is also a method of screening nucleotide sequences derived from mycobacteria in order to determine the presence of sequences corresponding to exported and/or secreted polypeptides which may be induced or repressed during the infection, their associated promoter and/or regulatory sequences which are capable in particular of allowing or promoting the export and/or secretion of said polypeptides of interest, or all or part of genes of interest encoding said polypeptides, characterized in that it uses a recombinant vector according to the invention.

The invention also relates to a method of screening, according to the invention, characterized in that it comprises the following steps:

a) physical fragmentation of the mycobacterial DNA sequences or their digestion with at least one defined enzyme and recovery of the fragments obtained;

b) insertion of the fragments obtained in step a) into a cloning site, which is compatible, where appropriate, with the enzyme of step a), of the polylinker of a vector according to the invention;

c) if necessary, amplification of said fragments contained in the vector, for example by replication of the latter after insertion of the vector thus modified into a defined cell, preferably *E. coli*;

d) transformation of the host cells with the vector amplified in step c), or in the absence of amplification, with the vector of step b);

e) culture of the transformed host cells in a medium allowing the detection of the export and/or

secretion marker, and/or of the promoter activity marker which is contained in the vector;

f) detection of the host cells which are positive (positive colonies) for the expression of the export and/or secretion marker, and/or of the promoter activity marker;

g) isolation of the DNA from the positive colonies and insertion of this DNA into a cell which is identical to that in step c);

h) selection of the inserts contained in the vector, allowing the production of clones which are positive for the export and/or secretion marker, and/or for the promoter activity marker;

i) isolation and characterization of the mycobacterial DNA fragments contained in these inserts.

In one of the preferred embodiments of the screening method according to the invention, the host cells, detected in step f), which are positive for the export and/or secretion marker are, optionally in a second stage, tested for the capacity of the selected nucleotide insert to stimulate the expression of the promoter activity marker when said host cells are phagocytosed by macrophage-type cells.

More specifically, the stimulation of the expression of the promoter activity marker in host cells placed in axenic culture (host cells alone in culture) is compared with the stimulation of the expression of the promoter activity marker in host cells cultured in the presence of macrophages and which are thus phagocytosed by the latter.

The selection of host cells which are positive for the promoter activity marker can be carried out

immediately after step e) of the method of screening described above, or alternatively after any one of steps f), g), h) or i), that is to say once the host cells have been positively selected for the export and/or selection  
5 marker.

The use of this method allows the construction of DNA libraries comprising sequences corresponding to polypeptides which are capable of being exported and/or secreted, and/or which are capable of being induced or  
10 repressed during the infection when they are produced inside recombinant mycobacteria. Step i) of the method may comprise a step for sequencing the inserts selected.

Preferably, in the method according to the invention, the vector used is chosen from the plasmids  
15 pJVEDa (CNCM, No. I-1797), pJVEDb (CNCM, No. I-1906), pJVEDc (CNCM, No. I-1799) or pJVED/M. tuberculosis (CNCM, No. I-1907), and the digestion of the mycobacterial DNA sequences is carried out by means of the enzyme Sau3A.

According to a preferred embodiment of the  
20 invention, the method of screening is characterized in that the mycobacterial sequences are derived from a pathogenic mycobacterium, for example from *M. tuberculosis*, *M. bovis*, *M. avium*, *M. africanum* or *M. leprae*.

The invention also comprises a library of genomic  
25 DNA or of cDNA which is complementary to mycobacterial mRNA, characterized in that it is obtained by a method comprising steps a) and b) or a), b) and c) of the preceding method according to the invention, preferably a library of genomic DNA or of cDNA which is complementary to  
30 mRNA of pathogenic mycobacteria, preferably of mycobacteria

belonging to the *Mycobacterium tuberculosis* complex group, preferably of *Mycobacterium tuberculosis*.

In the present invention, "nucleic sequences" or "amino acid sequences" are understood to designate SEQ ID No. X to SEQ ID No. Y, where X and Y may independently represent a number or an alphanumeric character, respectively the set of nucleic sequences or the set of amino acid sequences represented by figures X to Y, ends included.

~~For example, the nucleic sequences or the amino acid sequences SEQ ID No. 1 to SEQ ID No. 4N are respectively the nucleic sequences or the amino acid sequences represented by figures 1 to 4N, that is to say respectively the nucleic sequences or the amino sequences SEQ ID No. 1, SEQ ID No. 1A', SEQ ID No. 1B', SEQ ID No. 1C', SEQ ID No. 1D, SEQ ID No. 1F, SEQ ID No. 2, SEQ ID No. 3A, SEQ ID No. 3B, SEQ ID No. 3C, SEQ ID No. 4A, SEQ ID No. 4B, SEQ ID No. 4C, SEQ ID No. 4A', SEQ ID No. 4B', SEQ ID No. 4C', SEQ ID No. 4F, SEQ ID No. 4J, SEQ ID No. 4K, SEQ ID No. 4L, SEQ ID No. 4M, and SEQ ID No. 4N.~~

For example, the nucleic sequences or the amino acid sequences SEQ ID NOS: 1-87 are respectively the nucleic sequences or the amino acid sequences represented by figures 1 to 4N.

The subject of the invention is also the nucleotide sequences of mycobacteria or comprising nucleotide sequences of mycobacteria selected after carrying out the method according to the invention which is described above.

Preferably, said mycobacterium is chosen from ~~M. tuberculosis, M. bovis, M. africanum, M. avium,~~

~~M. leprae, M. paratuberculosis, M. kansasii or M. xenopi~~  
M. tuberculosis, M. bovis, M. africanum, M. avium,  
M. leprae, M. paratuberculosis, M. kansasii or M. xenopi.

The nucleotide sequences of mycobacteria or

5 comprising a mycobacterial nucleotide sequence are preferred, said mycobacterial nucleotide sequence being chosen from the sequences of mycobacterial DNA fragments having the nucleic sequences ~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A to SEQ ID No. 27C, SEQ ID No. 29,~~

10 ~~and SEQ ID No. 31A to SEQ ID No. 50F,~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, 35, 41, 46, 52, 56, 62, 64, 67, 69, 72, 74, 76, 78, 81, 84, 86, 88, 90, 92, 96, 98, 100, 104, 106, 108, 110, 113, 119, 122, 128, 133, 137, 139, 141, 143, 145, 148, 150, 152, 154, 156, 158, 160, 162, 165, 169, 177, 184, 189,

15 195, 200, 202, 206, 209, 211, 213, 217, 220, 225, 228, 238, 246, 250, 255, 258, 260, 262, 268, 274, 278, 280, 282, 284, 286, 288, 290, 297, 310, 317, 321, 323, 325, 327, 331, 333, 335, 337, 339, 346, 347, 353, 357, 359, 361, 364, 368, 371, 374, 380, 383, 385, 387, 389, 393, 395, 397, 399, 403, 405,

20 407, 410, 412, 419, 421, 426, 429, 431, 433, 437, 441, 447, 452, 456, 459, 461, 463, 469, 472, 474, 476, 482, 485, 487, 489, 495, 497, 501, 505, 510, 516, 519, 522, 530, 534, 537, 544, 546, 550, 552, 554, 556, 558, 564, 569, 571, 573, 576, 580, 584, 586, 588, 590, 594, 596, 598, 600, 604, 608,

25 610, 612, 614, 616, 618, 620, 622, 624, 626, 629, 631, 633, 635, 640, 647, 649, 651, 653, 657, 660, 662, 664, 666, 669, 674, 676, 678, 683, 686, 691, 693, 695, 697, 702, 717, 728, 733, 736, 739, 741, 743, 746, 752, 755, 757, 759, 761, 764, 767, 769, 771, 784, 794, 805, 807, 809, 811, 813, 817, 821,

30 823, 825, 827, 831, 833, 835, 837, 839, 842, 844, 846, 848, 864, 878, 883, 885, 887, 895, 901, 907, and 909.—which are

represented respectively by Figures 1 to 24C (plates 1 to 150), by Figures 27A to 27C (plates 152 to 154), by Figure 129 (plate 156) and by Figures 31A to 50F (plates 158 to 275).

- 5                   According to a specific embodiment of the invention, preferred sequences are, for example, the mycobacterial DNA fragments having the sequence ~~SEQ ID No. 1, SEQ ID No. 3A, SEQ ID No. 5A, SEQ ID No. 6A, SEQ ID No. 7A, SEQ ID No. 8A, SEQ ID No. 9A, SEQ ID No.~~
- 10 ~~10A, SEQ ID No. 27A or SEQ ID No. 29, which are contained respectively in the vectors pDP428 (CNCM, No. I-1818), p6D7 (CNCM, No. I-1814), p5F6 (CNCM, No. I-1816), p2A29 (CNCM, No. I-1817), p5B5 (CNCM, No. I-1819), p1C7 (CNCM, No. I-1820), p2D7 (CNCM,~~
- 15 ~~No. I-1821), p1B7 (CNCM, No. I-1843), p5A3 (CNCM, No. I-1815) and pM1C25 (CNCM, No. I-2062) SEQ ID NO: 1, which is contained in the vector pDP428 (CNCM, No. I-1818), SEQ ID NO: 41, which is contained in the vector p6D7 (CNCM, No. I-1814), SEQ ID NOS: 88 and 96, which are contained in~~
- 20 ~~the vector p5F6 (CNCM, No. I-1816), SEQ ID NO: 110, which is contained in the vector p2A29 (CNCM, No. I-1817), SEQ ID NO: 122, which is contained in the vector p5B5 (CNCM, No. I-1819), SEQ ID NOS: 137 and 143, which are contained in the vector p1C7 (CNCM, No. I-1820), SEQ ID NO:~~
- 25 ~~158, which is contained in the vector p2D7 (CNCM, No. I-1821), SEQ ID NO: 165, which is contained in the vector p1B7 (CNCM, No. I-1843), SEQ ID NO: 530, which is contained in the vector p5A3 (CNCM, No. I-1815), or SEQ ID NO: 544, which is contained in the vector pM1C25~~
- 30 ~~(CNCM, No. I-2062).~~

The invention also relates to a nucleic acid comprising the entire open reading frame of one of the nucleotide sequences according to the invention, in particular one of the sequences ~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A, SEQ ID No. 27C, SEQ ID No. 29, and SEQ ID No. 31A, to SEQ ID No. 50F~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, 35, 41, 46, 52, 56, 62, 64, 67, 69, 72, 74, 76, 78, 81, 84, 86, 88, 90, 92, 96, 98, 100, 104, 106, 108, 110, 113, 119, 122, 128, 133, 137, 139, 141, 143, 145, 148, 150, 152, 154, 156, 158, 160, 162, 165, 169, 177, 184, 189, 195, 200, 202, 206, 209, 211, 213, 217, 220, 225, 228, 238, 246, 250, 255, 258, 260, 262, 268, 274, 278, 280, 282, 284, 286, 288, 290, 297, 310, 317, 321, 323, 325, 327, 331, 333, 335, 337, 339, 346, 347, 353, 357, 359, 361, 364, 368, 371, 374, 380, 383, 385, 387, 389, 393, 395, 397, 399, 403, 405, 407, 410, 412, 419, 421, 426, 429, 431, 433, 437, 441, 447, 452, 456, 459, 461, 463, 469, 472, 474, 476, 482, 485, 487, 489, 495, 497, 501, 505, 510, 516, 519, 522, 530, 534, 537, 544, 546, 550, 552, 554, 556, 558, 564, 569, 571, 573, 576, 580, 584, 586, 588, 590, 594, 596, 598, 600, 604, 608, 610, 612, 614, 616, 618, 620, 622, 624, 626, 629, 631, 633, 635, 640, 647, 649, 651, 653, 657, 660, 662, 664, 666, 669, 674, 676, 678, 683, 686, 691, 693, 695, 697, 702, 717, 728, 733, 736, 739, 741, 743, 746, 752, 755, 757, 759, 761, 764, 767, 769, 771, 784, 794, 805, 807, 809, 811, 813, 817, 821, 823, 825, 827, 831, 833, 835, 837, 839, 842, 844, 846, 848, 864, 878, 883, 885, 887, 895, 901, 907, and 909 according to the invention. Said nucleic acid may be isolated, for example, in the following manner:

- a) preparation of a cosmid library from the *M. tuberculosis* DNA, for example according to the technique described by Jacobs et al., 1991;
- b) hybridization of all or part of a probe nucleic acid
- 5 having the sequences chosen, for example, from ~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A to SEQ ID No. 27C, SEQ ID No. 29, and SEQ ID No. 31 to SEQ ID No. 50F~~
- 10 SEQ ID NOS: 1, 8, 14, 25, 31, 33, 35, 41, 46, 52, 56, 62, 64, 67, 69, 72, 74, 76, 78, 81, 84, 86, 88, 90, 92, 96, 98,
- 100, 104, 106, 108, 110, 113, 119, 122, 128, 133, 137, 139,
- 141, 143, 145, 148, 150, 152, 154, 156, 158, 160, 162, 165,
- 169, 177, 184, 189, 195, 200, 202, 206, 209, 211, 213, 217,
- 220, 225, 228, 238, 246, 250, 255, 258, 260, 262, 268, 274,
- 15 278, 280, 282, 284, 286, 288, 290, 297, 310, 317, 321, 323,
- 325, 327, 331, 333, 335, 337, 339, 346, 347, 353, 357, 359,
- 361, 364, 368, 371, 374, 380, 383, 385, 387, 389, 393, 395,
- 397, 399, 403, 405, 407, 410, 412, 419, 421, 426, 429, 431,
- 433, 437, 441, 447, 452, 456, 459, 461, 463, 469, 472, 474,
- 476, 482, 485, 487, 489, 495, 497, 501, 505, 510, 516, 519,
- 20 522, 530, 534, 537, 544, 546, 550, 552, 554, 556, 558, 564,
- 569, 571, 573, 576, 580, 584, 586, 588, 590, 594, 596, 598,
- 600, 604, 608, 610, 612, 614, 616, 618, 620, 622, 624, 626,
- 629, 631, 633, 635, 640, 647, 649, 651, 653, 657, 660, 662,
- 664, 666, 669, 674, 676, 678, 683, 686, 691, 693, 695, 697,
- 25 702, 717, 728, 733, 736, 739, 741, 743, 746, 752, 755, 757,
- 759, 761, 764, 767, 769, 771, 784, 794, 805, 807, 809, 811,
- 813, 817, 821, 823, 825, 827, 831, 833, 835, 837, 839, 842,
- 844, 846, 848, 864, 878, 883, 885, 887, 895, 901, 907, and
- 909, with the cosmids of the library previously prepared in
- 30 step a);

- c) selection of the cosmids hybridizing with the probe nucleic acid of step b);
- d) sequencing of the DNA inserts of the clones selected in step c) and identification of the complete open reading
- 5 frame;
- e) where appropriate, cloning of the inserts sequenced in step d) into an appropriate expression and/or cloning vector.

The nucleic acids comprising the entire open

10 reading frame of the sequences ~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A to SEQ ID No. 27C, SEQ ID No. 29, and SEQ ID No. 31 to SEQ ID No. 50F~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, 35, 41, 46, 52, 56, 62, 64, 67, 69, 72, 74, 76, 78, 81, 84, 86, 88, 90, 92, 96, 98, 100, 104, 106, 108,

15 110, 113, 119, 122, 128, 133, 137, 139, 141, 143, 145, 148, 150, 152, 154, 156, 158, 160, 162, 165, 169, 177, 184, 189, 195, 200, 202, 206, 209, 211, 213, 217, 220, 225, 228, 238, 246, 250, 255, 258, 260, 262, 268, 274, 278, 280, 282, 284, 286, 288, 290, 297, 310, 317, 321, 323, 325, 327, 331, 333,

20 335, 337, 339, 346, 347, 353, 357, 359, 361, 364, 368, 371, 374, 380, 383, 385, 387, 389, 393, 395, 397, 399, 403, 405, 407, 410, 412, 419, 421, 426, 429, 431, 433, 437, 441, 447, 452, 456, 459, 461, 463, 469, 472, 474, 476, 482, 485, 487, 489, 495, 497, 501, 505, 510, 516, 519, 522, 530, 534, 537,

25 544, 546, 550, 552, 554, 556, 558, 564, 569, 571, 573, 576, 580, 584, 586, 588, 590, 594, 596, 598, 600, 604, 608, 610, 612, 614, 616, 618, 620, 622, 624, 626, 629, 631, 633, 635, 640, 647, 649, 651, 653, 657, 660, 662, 664, 666, 669, 674, 676, 678, 683, 686, 691, 693, 695, 697, 702, 717, 728, 733,

30 736, 739, 741, 743, 746, 752, 755, 757, 759, 761, 764, 767, 769, 771, 784, 794, 805, 807, 809, 811, 813, 817, 821, 823,

825, 827, 831, 833, 835, 837, 839, 842, 844, 846, 848, 864, 878, 883, 885, 887, 895, 901, 907, and 909 are among the preferred nucleic acids.

5 The present invention makes it possible to determine a gene fragment encoding an exported polypeptide. Comparison with the genome sequence published by Cole et al. (Cole et al., 1998, Nature, 393, 537-544) makes it possible to determine the whole gene carrying the identified sequence according to the present invention.

10 Nucleotide sequence comprising the entire open reading frame of a sequence according to the invention is understood to mean the nucleotide sequence (genomic, cDNA, semisynthetic or synthetic) comprising one of the sequences according to the invention and extending, on the one hand,  
15 in 5' of these sequences up to the first codon for initiation of translation (ATG or GTG) or even up to the first stop codon, and, on the other hand, in 3' of these sequences up to the next stop codon, this being in any one of the three possible reading frames.

20 The nucleotide sequences which are complementary to the above sequences according to the invention also form part of the invention.

Polynucleotide having a sequence which is complementary to a nucleotide sequence according to the  
25 invention is understood to mean any DNA or RNA sequence whose nucleotides are complementary to those of said sequence according to the invention and whose orientation is reversed.

30 The nucleotide fragments of the above sequences according to the invention, which are in particular useful as probes or primers, also form part of the invention.

The invention also relates to the polynucleotides, characterized in that they comprise a polynucleotide chosen from:

- a) a polynucleotide whose sequence is complementary to  
5 the sequence of a polynucleotide according to the invention,
- b) a polynucleotide whose sequence comprises at least 50% identity with a polynucleotide according to the invention,
- c) a polynucleotide which hybridizes, under high  
10 stringency conditions, with a polynucleotide sequence according to the invention,
- d) a fragment of at least 8 consecutive nucleotides of a polynucleotide defined according to the invention.

The high stringency conditions as well as the  
15 percentage identity will be defined below in the present description.

When the coding sequence derived from the export and/or secretion marker gene is a sequence derived from the *phoA* gene, the export and/or secretion of the product of  
20 the *phoA* gene, truncated where appropriate, is obtained only when this sequence is inserted in phase with the sequence or element for regulating the expression of the production of polynucleotides and its location placed upstream, which contains the elements controlling the  
25 expression, export and/or secretion which are derived from a mycobacterial sequence.

The recombinant vectors of the invention may of course comprise multiple cloning sites which are shifted by one or two nucleotides relative to a vector according to  
30 the invention, thus making it possible to express the polypeptide corresponding to the mycobacterial DNA fragment

which is inserted and which is capable of being translated according to one of the three possible reading frames.

For example, the preferred vectors pJVEDb and pJVEDc of the invention are distinguishable from the preferred vector pJVEDa by a respective shift of one and two nucleotides at the level of the multiple cloning site.

Thus, the vectors of the invention are capable of expressing each of the polypeptides which are capable of being encoded by an inserted mycobacterial DNA fragment. Said polypeptides, characterized in that they are therefore capable of being exported and/or secreted, and/or induced or repressed, or expressed constitutively during the infection, form part of the invention.

The polypeptides of the invention whose amino acid sequences are chosen from the amino acid sequences ~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A to SEQ ID No. 28, and SEQ ID No. 30 to SEQ ID No. 50F~~ SEQ ID NOS: 2-7, 9-13, 15-24, 26-30, 32, 34, 36-40, 42-45, 47-51, 53-55, 57-61, 63, 65-66, 68, 70-71, 73, 75, 77, 79-80, 82-83, 85, 87, 89, 91, 93-95, 97, 99, 101-103, 105, 107, 109, 111-112, 114-118, 120-121, 123-127, 129-132, 134-136, 138, 272-273, 140, 142, 144, 146-147, 149, 151, 153, 155, 157, 159, 161, 163-164, 166-168, 170-176, 178-183, 185-188, 190-194, 196-199, 201, 203-205, 207-208, 210, 212, 214-216, 218-219, 221-224, 226-227, 923-925, 229-237, 239-245, 247-249, 251-254, 256-257, 259, 261, 263-267, 269-271, 275-277, 279, 281, 283, 285, 287, 289, 291-296, 298-309, 311-316, 318-320, 322, 324, 326, 328-330, 332, 334, 336, 338, 340-345, 348-352, 354-356, 358, 360, 926-930, 362-363, 365-367, 369-370, 372-373, 375-379, 381-382, 384, 386, 388, 390-392, 394, 396, 398, 400-402, 404, 406, 408-409, 411,

838, 840-841, 843, 845, 847, 849-863, 865-877, 879-882,  
884, 886, 888-894, 896-900, 902-906, 908, 910, and  
represented respectively by Figures 1 to 24C (plates 1 to  
150), Figures 27A to 28 (plates 152 to 155) and Figures 30  
20 to 50F (plates 157 to 275) are in particular preferred.

Also forming part of the invention are the  
fragments or biologically active fragments as well as the  
polypeptides which are homologous to said polypeptides;  
fragment, biologically active fragment and polypeptides  
25 which are homologous to a polypeptide being as defined  
below in the description.

The invention also relates to the polypeptides  
comprising a polypeptide or one of their fragments  
according to the invention.

30 The subject of the invention is also recombinant  
mycobacteria containing a recombinant vector according to

the invention which is described above. A preferred mycobacterium is a mycobacterium of the *M. smegmatis* type.

*M. smegmatis* advantageously makes it possible to test the efficiency of mycobacterial sequences for  
5 controlling the expression, export and/or secretion, and/or promoter activity of a given sequence, for example of a sequence encoding a marker such as alkaline phosphatase and/or luciferase.

Another preferred mycobacterium is a myco-  
10 bacterium of the *M. bovis* type, for example the BCG strain which is currently used for vaccination against tuberculosis.

Another preferred mycobacterium is a strain of *M. tuberculosis*, *M. bovis* or *M. africanum* potentially  
15 possessing all the appropriate regulatory systems.

The inventors have thus characterized, in particular, a polynucleotide consisting of a nucleotide sequence which is present in all the tested strains of mycobacteria belonging to the *Mycobacterium tuberculosis*  
20 complex. This polynucleotide, called DP428, contains an open reading frame (ORF) encoding a polypeptide of about 12 kD. The open reading frame (ORF) encoding the polypeptide DP428 extends from the nucleotide at position nt 941 to the nucleotide at position nt 1351 of the  
25 sequence ~~SEQ ID No. 2~~, SEQ ID NO: 35, the polypeptide DP428 having the following amino acid sequences ~~SEQ ID No. 28~~, SEQ ID NOS: 39 & 543:

MKTGTATRRRLAVLIALALPGAVALLAEPSATGASDPCAASEVARTVGSVAKSMGD  
YLDSPETNQVMTAVLQQQVGPGSVASLKAHFEANPKVASDLHALSQPLTDLSTRCSLP  
30 ISGLQAIGLMQAVQGARR.

This molecular weight (MW) corresponds to the theoretical MW of the mature protein obtained after cleavage of the signal sequence, the MW of the protein or polypeptide DP428 being about 10 kD after potential anchorage to peptidoglycan and potential cleavage between S and G of the LPISG motif.

This polynucleotide includes, on the one hand, an open reading frame corresponding to a structural gene and, on the other hand, the signals for regulating the expression of the coding sequence upstream and downstream of the latter. The polypeptide DP428 is composed of a signal peptide, a hydrophilic central region and a hydrophobic C-terminal region. The latter ends with two arginine residues (R), a retention signal, and is preceded by an LPISG motif which resembles the LPXTG motif for anchorage to peptidoglycan (Schneewind et al., 1995).

Structural gene for the purposes of the present invention is understood to mean a polynucleotide encoding a protein, a polypeptide or alternatively a fragment of the latter, said polynucleotide comprising only the sequence corresponding to the open reading frame (ORF), which excludes the sequences on the 5' side of the open reading frame (ORF) which direct the initiation of transcription.

Thus, the invention relates in particular to a polynucleotide whose sequence is chosen from the nucleotide sequences ~~SEQ ID No. 1~~ to ~~SEQ ID No. 2~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, and 35.

More particularly, the invention relates to a polynucleotide, characterized in that it comprises a polynucleotide chosen from:

- a) a polynucleotide whose sequence is chosen from the nucleotide sequences ~~SEQ ID No. 1~~ to ~~SEQ ID No. 2~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, and 35,
- 5 b) a polynucleotide whose nucleic sequence is the sequence between the nucleotide at position nt 964 and the nucleotide at position nt 1234, ends included, of the sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33,
- 10 c) a polynucleotide whose sequence is complementary to the sequence of a polynucleotide defined in a) or b),
- d) a polynucleotide whose sequence exhibits at least 50% identity with a polynucleotide defined in a), b) or c),
- e) a polynucleotide which hybridizes, under high stringency conditions, with a sequence of a polynucleotide
- 15 defined in a), b), c) or d),
- f) a fragment of at least 8 consecutive nucleotides of a polynucleotide defined in a), b), c), d) or e).

Nucleotide sequence, polynucleotide or nucleic acid is understood to mean, according to the present

20 invention, a double-stranded DNA, a single-stranded DNA and products of transcription of said DNAs.

Percentage identity for the purpose of the present invention is understood to mean a percentage identity between the bases of two polynucleotides, this

25 percentage being purely statistical and the differences between the two polynucleotides being distributed randomly and over their entire length.

Hybridization under high stringency conditions means that the temperature and ionic strength conditions

30 are chosen such that they allow the hybridization between two complementary DNA fragments to be maintained.

By way of illustration, high stringency conditions of the hybridization step for the purposes of defining the polynucleotide fragments described above are advantageously the following:

5           the hybridization is carried out at a temperature which is preferably 65°C, in the presence of buffer marketed under the name rapid-hyb buffer by Amersham (RPN 1636) and 100 µg/ml of *E. coli* DNA.

10           The washing steps may, for example, be the following:

- two washes of 10 min, preferably at 65°C, in a 2 × SSC buffer and 0.1% SDS;
- two washes of 10 min, preferably at 65°C, in a 1 × SSC buffer and 0.1% SDS;
- 15 - one wash of 10 min, preferably at 65°C, in a 0.1 × SSC buffer and 0.1% SDS.

20           1 × SSC corresponds to 0.15 M NaCl and 0.05 M Na citrate and a 1 × Denhardt solution corresponds to 0.02% Ficoll, 0.02% of polyvinylpyrrolidone and 0.02% of bovine serum albumin.

Advantageously, a nucleotide fragment corresponding to the preceding definition will have at least 8 nucleotides, preferably at least 12 nucleotides, and still more preferably at least 20 consecutive nucleotides  
25 of the sequence from which it is derived. The high stringency hybridization conditions described above for a polynucleotide having a size of about 200 bases will be adjusted by persons skilled in the art for oligonucleotides with a larger or a smaller size, according to the teaching  
30 of Sambrook et al., 1989.

For the conditions for using the restriction enzymes with the aim of obtaining nucleotide fragments of the polynucleotides according to the invention, reference will be advantageously made to the manual by Sambrook  
5 et al., 1989.

Advantageously, a polynucleotide of the invention will contain at least one sequence comprising the stretch of nucleotides going from the nucleotide at position nt 964 to the nucleotide nt 1234 of the polynucleotide having the  
10 sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33.

The subject of the present invention is a polynucleotide according to the invention, characterized in that its nucleic sequence hybridizes with the DNA of a  
15 sequence of mycobacteria and preferably with the DNA of a sequence of mycobacteria belonging to the *Mycobacterium tuberculosis* complex.

The polynucleotide is encoded by a polynucleotide sequence as described supra.

20 The subject of the present invention is also a polypeptide derived from a mycobacterium, characterized in that it is present only in the mycobacteria belonging to the *Mycobacterium tuberculosis* complex.

The invention also relates to a polypeptide  
25 characterized in that it comprises a polypeptide chosen from:

a) a polypeptide whose amino acid sequence is included in an amino acid sequence chosen from the amino acid sequences  
~~SEQ ID No. 1 to SEQ ID No. 24C, SEQ ID No. 27A to~~  
30 ~~SEQ ID No. 27C, SEQ ID No. 29, and SEQ ID No. 31A to~~

- 10 291-296, 298-309, 311-316, 318-320, 322, 324, 326, 328-330, 332, 334, 336, 338, 340-345, 348-352, 354-356, 358, 360, 926-930, 362-363, 365-367, 369-370, 372-373, 375-379, 381-382, 384, 386, 388, 390-392, 394, 396, 398, 400-402, 404, 406, 408-409, 411, 413-418, 420, 422-425, 427-428, 430,
- 15 432, 434-436, 438-440, 442-446, 448-451, 453-455, 457-458, 460, 462, 464-468, 470-471, 473, 475, 477-481, 483-484, 486, 488, 490-494, 496, 498-500, 502-504, 506-509, 511-515, 517-518, 520-521, 523-527, 531-533, 535-536, 538-542, 543, 545, 547-549, 551, 553, 555, 557, 559-563, 565-568, 570,
- 20 572, 574-575, 577-579, 581-583, 585, 587, 589, 591-593, 595, 597, 599, 601-603, 605-607, 609, 611, 613, 615, 617, 619, 621, 623, 625, 627-628, 630, 632, 634, 636-639, 641-646, 648, 650, 652, 654-656, 658-659, 661, 663, 665, 931-933, 667-668, 670-673, 675, 677, 679-682, 684-685, 687-690,
- 25 692, 694, 696, 698-701, 703-716, 718-727, 729-732, 734-735, 737-738, 740, 742, 744-745, 747-751, 753-754, 756, 758, 760, 762-763, 765-766, 768, 770, 772-783, 785-793, 795-804, 806, 808, 810, 812, 814-816, 818-820, 822, 824, 826, 828-830, 832, 834, 836, 838, 840-841, 843, 845, 847, 849-863,
- 30 865-877, 879-882, 884, 886, 888-894, 896-900, 902-906, 908, 910,

- b) a polypeptide which is homologous to the polypeptide defined in a),
- c) a fragment of at least 5 amino acids of a polypeptide defined in a) or b),
- 5 d) a biologically active fragment of a polypeptide defined in a), b) or c).

The subject of the present invention is also a polypeptide whose amino acid sequence is included in the amino acid sequences ~~SEQ ID No. 1 or SEQ ID No. 2~~  
10 SEQ ID NOS: 2-7, 9-13, 15-24, 26-30, 32, 34, 36-40, or a polypeptide having the amino acid sequence ~~SEQ ID No. 28~~  
SEQ ID NO: 543.

Homologous polypeptide will be understood to designate the polypeptides exhibiting, relative to the  
15 natural polypeptide according to the invention such as the polypeptide DP428, certain modifications such as in particular a deletion, addition or substitution of at least one amino acid, a truncation, an extension, a chimeric fusion, and/or a mutation. Among the homologous  
20 polypeptides, those whose amino acid sequence exhibits at least 30%, preferably 50%, homology with the amino acid sequences of the polypeptides according to the invention are preferred. In the case of a substitution, one or more consecutive or nonconsecutive amino acids are replaced with  
25 "equivalent" amino acids. The expression "equivalent" amino acid is intended here to designate any amino acid capable of being substituted for one of the amino acids of the parent structure without, however, essentially modifying the immunogenic properties of the corresponding peptides.  
30 In other words, the equivalent amino acids will be those which allow the production of a polypeptide having a

modified sequence which allows the induction *in vivo* of antibodies or of cells capable of recognizing the polypeptide whose amino acid sequence is included in the amino acid sequence of the polypeptide according to the  
5 invention, such as the amino acid sequences ~~SEQ ID No. 1 to~~  
~~SEQ ID No. 2~~ SEQ ID NOS: 2-7, 9-13, 15-24, 26-30, 32, 34,  
36-40, or a polypeptide having the amino acid sequence ~~SEQ~~  
~~ID No. 28~~ SEQ ID NO: 543 (polypeptide DP428) or one of its  
above-defined fragments.

10               These equivalent aminoaclys may be determined  
either based on their structural homology with the  
aminoaclys for which they are substituted, or on the  
results of cross-immunogenicity assays to which the  
different peptides are capable of giving rise.

15               By way of example, there may be mentioned the  
possibilities of substitutions which are capable of being  
made without resulting in a profound modification of the  
immunogenicity of the corresponding modified peptides, the  
replacements, for example, of leucine with valine or  
20 isoleucine, of aspartic acid with glutamic acid, of  
glutamine with asparagine and of arginine with lysine, and  
the like, it being possible to naturally envisage the  
reverse substitutions under the same conditions.

25               Biologically active fragment will be understood  
to designate in particular a fragment of an amino acid  
sequence of a polypeptide having at least one of the  
characteristics of the polypeptides according to the  
invention, in particular in that it is:

- capable of being exported and/or secreted by a  
30 mycobacterium, and/or of being induced or repressed during  
infection with the mycobacterium; and/or

- capable of inducing, repressing or modulating, directly or indirectly, a mycobacterium virulence factor; and/or
  - capable of inducing an immunogenicity reaction
- 5 directed against mycobacteria; and/or
- capable of being recognized by an antibody which is specific for mycobacterium.

Polypeptide fragment is understood to designate a polypeptide comprising a minimum of 5 amino acids,

10 preferably 10 amino acids and 15 amino acids.

A polypeptide of the invention, or one of its fragments, as defined above, is capable of being specifically recognized by the antibodies present in the serum of patients infected by mycobacteria and preferably

15 bacteria belonging to the *Mycobacterium tuberculosis* complex or by cells of the infected host.

Thus, forming part of the invention are the fragments of the polypeptide whose amino acid sequence is included in the amino acid sequence of a polypeptide

20 according to the invention, such as the amino acid sequences ~~SEQ ID No. 1 to SEQ ID No. 2~~ SEQ ID NOS: 2-7, 9-13, 15-24, 26-30, 32, 34, 36-40, or a polypeptide having an amino acid sequence ~~SEQ ID No. 28~~ SEQ ID NO: 543, which may be obtained by cleavage of said polypeptide with a

25 proteolytic enzyme, such as trypsin or chymotrypsin or collagenase, or with a chemical reagent, such as cyanogen bromide (CNBr) or alternatively by placing a polypeptide according to the invention such as the polypeptide DP428 in a very acidic environment, for example at pH 2.5. Preferred

30 peptide fragments according to the invention, for use in diagnosis or in vaccination, are the fragments contained in

regions of a polypeptide according to the invention such as the polypeptide DP428 which are capable of being naturally exposed to the solvent and to thus exhibit substantial immunogenicity properties. Such peptide fragments may be prepared either by chemical synthesis, from hosts transformed with an expression vector according to the invention containing a nucleic acid allowing the expression of said fragments, placed under the control of appropriate regulatory and/or expression elements or alternatively by chemical or enzymatic cleavage.

Analysis of the hydrophilicity of the polypeptide DP428 was carried out with the aid of the DNA Strider<sup>TM</sup> software (marketed by CEA Saclay) on the basis of a calculation of the hydrophilic character of the region encoding DP428 of ~~SEQ ID No. 28~~ SEQ ID NO: 543. The results of this analysis are presented in Figure 54 where the hydrophilicity index is detailed, for each of the amino acids (AA) having a defined position in ~~SEQ ID No. 28~~ SEQ ID NO: 543. The higher the hydrophilicity index, the more the amino acid considered is likely to be exposed to the solvent in the native molecule, and is subsequently likely to exhibit a high degree of antigenicity. Thus, a stretch of at least seven amino acids possessing a high hydrophilicity index ( $>0.3$ ) can constitute the basis of the structure of an immunogenic candidate peptide according to the present invention.

The cellular immune responses of the host to a polypeptide according to the invention can be demonstrated according to the techniques described by Colignon et al., 1996.

From the data of the hydrophilicity map presented in figure 54, the inventors were able to define regions of the polypeptide DP428 which are preferably exposed to the solvent, more particularly the region located between amino acids 55 and 72 of the sequence ~~SEQ ID No. 28~~ SEQ ID NO: 543 and the region located between amino acids 99 and 107 of ~~SEQ ID No. 28~~ SEQ ID NO: 543.

The peptide regions of the polypeptide DP428 which are defined above may be advantageously used for the production of immunogenic compositions or of vaccine compositions according to the invention.

The polynucleotides characterized in that they encode a polypeptide according to the invention also form part of the invention.

The invention also relates to the nucleic acid sequences which can be used as probes or primers, characterized in that said sequences are chosen from the nucleic acid sequences of polynucleotides according to the invention.

The invention relates, in addition, to the use of a nucleic acid sequence of polynucleotides according to the invention as a probe or a primer for the detection and/or amplification of a nucleic acid sequence. Among these nucleic acid sequences according to the invention which can be used as probes or primers there are preferred the nucleic acid sequences of the invention, characterized in that said sequences are sequences, or their complementary sequence, between the nucleotide at position nt 964 and the nucleotide at position nt 1234, ends included, of the sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33.

Among the polynucleotides according to the invention which can be used as nucleotide primers, the polynucleotides having the sequences ~~SEQ ID No. 25~~ SEQ ID NO: 528 ~~SEQ ID No. 26~~ and SEQ ID NO: 529 are particularly preferred.

The polynucleotides according to the invention may thus be used to select nucleotide primers, in particular for the PCR technique (Erlich, 1989; Innis et al., 1990, and, Rolfs et al., 1991).

This technique requires the choice of oligonucleotide pairs flanking the fragment which has to be amplified. Reference may be made, for example, to the technique described in American patent US No. 4,683,202. These oligodeoxyribonucleotide or oligoribonucleotide primers advantageously have a length of at least 8 nucleotides, preferably of at least 12 nucleotides, and still more preferably of at least 20 nucleotides. Primers having a length of between 8 and 30 and preferably 12 and 22 nucleotides will be preferred in particular. One of the two primers is complementary to the (+) strand [forward primer] of the template and the other primer is complementary to the (-) strand [backward primer]. It is important that the primers do not possess a secondary structure or sequences which are complementary to each other. Moreover, the length and the sequence of each primer should be chosen so that the primers do not hybridize with other nucleic acids from prokaryotic or eukaryotic cells, in particular with the nucleic acids from other pathogenic mycobacteria, or with human DNA or RNA which may possibly contaminate the biological sample.

The results presented in Figure 51 show that the sequence encoding the polypeptide DP428 (~~SEQ ID No. 28~~ SEQ ID NO: 543) is not found in the DNAs of *M. fortuitum*, *M. simiae*, *M. avium*, *M. chelonae*, *M. flavescens*,  
5 *M. gordoniae*, *M. marinum* and *M. kansasii*.

The amplified fragments may be identified after agarose or polyacrylamide gel electrophoresis or after capillary electrophoresis, or alternatively after a chromatographic technique (gel filtration, hydrophobic  
10 chromatography or ion-exchange chromatography). The specificity of the amplification may be checked by molecular hybridization using, as probes, the nucleotide sequences of polynucleotides of the invention, plasmids containing these sequences or their amplification products.

15 The amplified nucleotide fragments may be used as reagents in hybridization reactions in order to detect the presence, in a biological sample, of a target nucleic acid having a sequence which is complementary to that of said amplified nucleotide fragments.

20 Among the polynucleotides according to the invention which can be used as nucleotide probes, the polynucleotide fragment comprising the sequence between the nucleotide at position nt 964 and the nucleotide at position nt 1234, ends included, of the sequences ~~SEQ ID~~  
25 ~~No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33 is most particularly preferred.

These probes and amplicons may be labeled or otherwise with radioactive elements or with nonradioactive molecules such as enzymes or fluorescent elements.

30 The invention also relates to the nucleotide fragments which are capable of being obtained by

amplification with the aid of primers according to the invention.

Other techniques for the amplification of the target nucleic acid may be advantageously used as  
5 alternatives to PCR.

The SDA (Strand Displacement Amplification) technique (Walker et al., 1992) is an isothermal amplification technique whose principle is based on the capacity of a restriction enzyme to cut one of the two  
10 strands of its recognition site which is in the form of a hemiphosphorothioate and on the property of a DNA polymerase to initiate the synthesis of a new DNA strand from the 3'OH end created by the restriction enzyme and to displace the strand previously synthesized which is present  
15 downstream.

The polynucleotides of the invention, in particular the primers according to the invention, may also be used in other methods of amplifying a target nucleic acid, such as:

- 20 - the TAS (Transcription-based Amplification System) technique described by Kwoh et al. in 1989;
- the 3SR (Self-Sustained Sequence Replication) technique described by Guatelli et al. in 1990;
- the NASBA (Nucleic Acid Sequence Based Amplification)  
25 technique described by Kievitis et al. in 1991;
- the TMA (Transcription Mediated Amplification) technique.

The polynucleotides of the invention may also be used in techniques for the amplification or modification of  
30 the nucleic acid serving as probe, such as:

- the LCR (Ligase Chain Reaction) technique described by Landegren et al. in 1988 and improved by Barany et al. in 1991, which uses a heat-stable ligase;
- the RCR (Repair Chain Reaction) technique described by  
5 Segev in 1992;
- the CPR (Cycling Probe Reaction) technique described by Duck et al. in 1990;
- the Q-beta-replicase amplification technique described by Miele et al. in 1983 and improved in particular by  
10 Chu et al. in 1986, Lizardi et al. in 1988 and then by Burg et al. as well as Stone et al. in 1996.

In the case where the target polynucleotide to be detected is an RNA, for example an mRNA, a reverse transcriptase-type enzyme will be advantageously used,  
15 prior to using an amplification reaction using the primers according to the invention or to the use of a method of detection using the probes of the invention, in order to obtain a cDNA from the RNA contained in the biological sample. The cDNA obtained will then serve as target for the  
20 primers or probes used in the method of amplification or detection according to the invention.

The detection probe will be chosen so that it hybridizes with the amplicon generated. Such a detection probe will advantageously have a sequence of at least  
25 12 nucleotides in particular of at least 15 nucleotides and preferably at least 200 nucleotides.

The nucleotide probes according to the invention are capable of detecting mycobacteria and preferably bacteria belonging to the *Mycobacterium tuberculosis*  
30 complex, more particularly because of the fact that these mycobacteria possess in their genome at least one copy of

polynucleotides according to the invention. These probes according to the invention are capable, for example, of hybridizing with the nucleotide sequence of a polypeptide according to the invention, more particularly any  
5 oligonucleotide hybridizing with the sequences ~~SEQ ID No. 1~~  
SEQ ID NOS: 1, 8, 14, 25, 31, and 33 encoding the *M. tuberculosis* polypeptide DP428 and not exhibiting a cross-hybridization reaction or an amplification reaction (PCR) with, for example, sequences present in mycobacteria  
10 not belonging to the *Mycobacterium tuberculosis* complex. The nucleotide probes according to the invention hybridize specifically with a DNA or RNA molecule of a polynucleotide according to the invention, under high stringency hybridization conditions as given in the form of an example  
15 above.

The nonlabeled sequences may be used directly as probes. However, the sequences are generally labeled with a radioactive element ( $^{32}\text{P}$ ,  $^{35}\text{S}$ ,  $^3\text{H}$ ,  $^{125}\text{I}$ ) or with a nonradioactive molecule (biotin, acetylaminofluorene,  
20 digoxigenin, 5-bromodeoxyuridine, fluorescein) in order to obtain probes which can be used for many applications.

Examples of nonradioactive labelings of probes are described, for example, in French patent No. 78,10975 or by Urdea et al. or by Sanchez-Pescador et al. in 1988.

25 In the latter case, it will also be possible to use one of the labeling methods described in patents FR 2,422,956 and FR 2,518,755. The hybridization technique may be carried out in various ways (Matthews et al., 1988). The most common method consists in  
30 immobilizing the nucleic acid extracted from mycobacterial cells onto a support (such as nitrocellulose, nylon,

polystyrene) and in incubating, under well-defined conditions, the immobilized target nucleic acid with the probe. After hybridization, the excess probe is removed and the hybrid molecules formed are detected by the appropriate  
5 method (measurement of the radioactivity, of the fluorescence or of the enzymatic activity linked to the probe).

Advantageously, the labeled nucleotide probes according to the invention may have a structure such that  
10 they make amplification of the radioactive or nonradioactive signal possible. An amplification system corresponding to the above definition will comprise detection probes in the form of a branched, ramified DNA such as those described by Urdea et al. in 1991. According  
15 to this technique, several types of probe, in particular a capture probe, to immobilize the target DNA or RNA to a support, and a detection probe will be advantageously used. The detection probe binds a "branched" DNA having a ramified structure. The branched DNA in turn is capable of  
20 binding oligonucleotide probes which are themselves coupled to alkaline phosphatase molecules. The activity of this enzyme is then detected using a chemiluminescent substrate, for example a derivative of dioxethane phosphate.

According to another advantageous embodiment of the  
25 nucleic probes according to the invention, they can be covalently or noncovalently immobilized on a support and used as capture probes. In this case, a probe termed "capture probe" is immobilized on a support and serves to capture, through specific hybridization, the target nucleic  
30 acid obtained from the biological sample to be tested. If necessary, the solid support is separated from the sample

and the duplex formed between the capture probe and the target nucleic acid is then detected by means of a second probe termed "detection probe" which is labeled with an easily detectable element.

- 5           The oligonucleotide fragments may be obtained from the sequences according to the invention by cleavage with restriction enzymes or by chemical synthesis according to conventional methods, for example according to the method described in European patent No. EP-0,305,929 (Millipore Corporation) or by other methods.

          An appropriate method of preparing the nucleic acids of the invention comprising a maximum of 200 nucleotides (or 200 bp in the case of double-stranded nucleic acids) comprises the following steps:

- 15   - synthesis of DNA using the automated beta-cyanethylphosphoramidite method described in 1986,  
- cloning of the nucleic acids thus obtained into an appropriate vector and recovery of the nucleic acids by hybridization with an appropriate probe.

- 20           A method of preparation, by the chemical route, of nucleic acids according to the invention having a length greater than 200 nucleotides (or 200 bp in the case of double-stranded nucleic acids) comprises the following steps:

- 25   - assembly of chemically synthesized oligonucleotides, provided at their end with different restriction sites, whose sequences are compatible with the stretch of amino acids of the natural polypeptide according to the principle described in 1983,

- cloning of the nucleic acids thus obtained into an appropriate vector and recovery of the desired nucleic acids by hybridization with an appropriate probe.

5 The nucleotide probes used for recovering the desired nucleic acids in the abovementioned methods generally consist of 8 to 200 nucleotides of the polypeptide sequence according to the invention and are capable of hybridizing with the nucleic acid tested for under the hybridization conditions defined above. The  
10 synthesis of these probes may be carried out according to the automated beta-cyanethylphosphoramidite method described in 1986.

The oligonucleotide probes according to the invention may be used in a detection device comprising an  
15 oligonucleotide array library. An exemplary embodiment of such an array library may consist of an array of probe oligonucleotides which are attached to a support, the sequence of each probe of a given length being situated with a shift of one or more bases relative to the preceding  
20 probe, each of the probes of the array arrangement thus being complementary to a distinct sequence of the target DNA or RNA to be detected and each probe of known sequence being attached at a predetermined position of the support. The target sequence to be detected may be advantageously  
25 labeled radioactively or nonradioactively. When the labeled target sequence is brought into contact with the array device, it forms hybrids with the probes having complementary sequences. A nuclease treatment, followed by washing, makes it possible to remove the probe-target  
30 sequence hybrids which are not perfectly complementary. Because of the precise knowledge of the sequence of a probe

at a given position of the array, it is then possible to deduce the nucleotide sequence of the target DNA or RNA sequence. This technique is particularly effective when matrices of oligonucleotide probes of a large size are  
5 used.

An alternative to the use of a labeled target sequence may consist of using a support allowing a "bioelectronic" detection of the hybridization of the target sequence with the probes of the array support, when  
10 said support consists of or comprises a material capable of acting, for example, as an electron donor at the positions of the array where a hybrid has been formed. Such an electron-donating material is for example gold. The detection of the nucleotide sequence of the target DNA or  
15 RNA is then determined by an electronic device.

An exemplary embodiment of a biosensor, as defined above, is described in European patent application No. EP-0,721,016 in the name of Affymax Technologies N.V. or in American patent No. US 5,202,231 in the name of  
20 Drmanac.

The subject of the invention is also the hybrid polynucleotides resulting:

- either from the formation of a hybrid molecule between an RNA or a DNA (genomic DNA or cDNA) obtained from a  
25 biological sample with a probe or a primer according to the invention,
- or from the formation of a hybrid molecule between an RNA or a DNA (genomic DNA or cDNA) obtained from a biological sample with a nucleotide fragment amplified with  
30 the aid of a pair of primers according to the invention.

cDNA for the purposes of the invention is understood to mean a DNA molecule obtained by causing a reverse transcriptase type enzyme to act on an RNA molecule, in particular a messenger RNA (mRNA) molecule,  
5 according to the techniques described in Sambrook et al. in 1989.

The subject of the present invention is also a family of recombinant plasmids, characterized in that they contain at least one nucleotide sequence of a  
10 polynucleotide according to the invention. According to an advantageous embodiment of said plasmid it comprises the nucleotide sequences SEQ ID No. 1 SEQ ID NOS: 1, 8, 14, 25, 31, and 33 or a fragment thereof.

Another subject of the present invention is a  
15 vector for the cloning, expression and/or insertion of a sequence, characterized in that it comprises a nucleotide sequence of a polynucleotide according to the invention at a site which is not essential for its replication, where appropriate under the control of regulatory elements  
20 capable of playing a role in the expression of the polypeptide DP428, in a given host.

Specific vectors are for example plasmids, phages, cosmids, phagemids and YACs.

These vectors are useful for transforming host  
25 cells so as to clone or express the nucleotide sequences of the invention.

The invention also comprises the host cells transformed with a vector according to the invention.

Preferably, the host cells are transformed under  
30 conditions allowing the expression of a recombinant polypeptide according to the invention.

A preferred host cells according to the invention is the *E. coli* strain transformed with the plasmid pDP428 deposited on 28 January 1997 at the CNCM under the No. I-1818 or transformed with the plasmid pM1C25 which was  
5 deposited on 4 August 1998 at the CNCM under the No. I-2062 or a mycobacterium belonging to a strain of *M. tuberculosis*, *M. bovis* or *M. africanum* potentially possessing all the appropriate regulatory systems.

It is now easy to produce proteins or  
10 polypeptides in a relatively large quantity by genetic engineering using, as expression vectors, plasmids, phages or phagemids. All or part of the DP428 gene, or any polynucleotide according to the invention, may be inserted into an appropriate expression vector in order to produce  
15 *in vitro* a polypeptide according to the invention, in particular the polypeptide DP428. Said polypeptide may be attached to a microplate in order to develop a serological test intended to search, for diagnostic purposes, for the specific antibodies in patients suffering tuberculosis.

20 Thus, the present invention relates to a method of preparing a polypeptide, characterized in that it uses a vector according to the invention. More particularly, the invention relates to a method of preparing a polypeptide of the invention comprising the following steps:

25 - where appropriate, the prior amplification, according to the PCR technique, of the quantity of nucleotide sequences encoding said polypeptide with the aid of two DNA primers chosen so that one of these primers is identical to the first 10 to 25 nucleotides of the nucleotide sequence  
30 encoding said polypeptide, while the other primer is complementary to the last 10 to 25 nucleotides (or

- hybridizes with these last 10 to 25 nucleotides) of said nucleotide sequence, or conversely so that one of these primers is identical to the last 10 to 25 nucleotides of said sequence, while the other primer is complementary to
- 5 the first 10 to 25 nucleotides (or hybridizes with the first 10 to 25 nucleotides) of said nucleotide sequence, followed by the introduction of said sequences thus amplified into an appropriate vector,
- the culture, in an appropriate culture medium, of a
- 10 cellular host which has been previously transformed with an appropriate vector containing a nucleic acid according to the invention comprising the nucleotide sequence encoding said polypeptide, and
- the separation, from said culture medium, of said
- 15 polypeptide produced by said transformed cellular host.

The subject of the invention is also a polypeptide which is capable of being obtained by a method of the invention as described above.

- The peptides according to the invention may also
- 20 be prepared by techniques which are conventionally used in the field of peptide synthesis. This synthesis may be carried out in homogeneous solution or in solid phase.

- For example, the technique of synthesis in homogeneous solution described by Houbenweyl in 1974 will
- 25 be used.

- This method of synthesis consists in successively condensing in pairs the successive aminoacyls in the required order, or in condensing aminoacyls and fragments formed beforehand and already containing several aminoacyls
- 30 in the appropriate order, or alternatively several fragments thus prepared beforehand, it being understood

that care will be taken to protect beforehand all the reactive functions carried by these aminoacyls or fragments, with the exception of the amine functions of one and the carboxyl functions of the other or vice versa, which should normally be involved in the formation of the peptide bonds, in particular after activation of the carboxyl function, according to methods well known in peptide synthesis. As a variant, use may be made of coupling reactions using conventional coupling reagents, of the carbodiimide type, such as for example 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide.

When the aminoacyl used possesses an additional acid function (in particular in the case of glutamic acid), these functions will be protected, for example with t-butyl ester groups.

In the case of gradual synthesis, amino acid by amino acid, the synthesis preferably starts with the condensation of the C-terminal amino acid with the amino acid which corresponds to the neighboring aminoacyl in the desired sequence, and so on, step by step, up to the N-terminal amino acid.

According to another preferred technique of the invention, the one described by Merrifield is used.

To manufacture a peptide chain according to the Merrifield method, use is made of a very porous polymer resin onto which the first C-terminal amino acid of the chain is attached. This amino acid is attached to the resin via its carboxyl group and its amine function is protected, for example with the t-butyloxycarbonyl group.

When the first C-terminal amino acid is thus attached to the resin, the group for protecting the amine function is removed by washing the resin with an acid.

In the case where the group for protecting the  
5 amine function is the t-butyloxycarbonyl group, it may be removed by treating the resin with trifluoroacetic acid.

The second amino acid which provides the second aminoacyl of the desired sequence, from the C-terminal aminoacyl residue, is then coupled with the deprotected  
10 amine function of the first C-terminal amino acid attached to the chain. Preferably, the carboxyl function of this second amino acid is activated, for example with dicyclohexylcarbodiimide, and the amine function is protected, for example with t-butyloxycarbonyl.

15 The first portion of the desired peptide chain is thus obtained which comprises two amino acids, and whose terminal amine function is protected. As before, the amine function is deprotected and it is then possible to proceed to the attachment of the third aminoacyl, under conditions  
20 similar to those for the addition of the second C-terminal amino acid.

The amino acids which will constitute the peptide chain will thus be attached, one after the other, to the amino group, each time deprotected beforehand, of the  
25 portion of the peptide chain which is already formed and which is attached to the resin.

When the entire desired peptide chain is formed, the groups for protecting the different amino acids constituting the peptide chain are removed and the peptide  
30 is detached from the resin, for example with the aid of hydrofluoric acid.

Preferably, said polypeptides which are capable of being obtained by a method of the invention as described above will comprise a region exposed to the solvent and will have a length of at least 20 amino acids.

5           According to another embodiment of the invention, said polypeptides are specific to mycobacteria of the *Mycobacterium tuberculosis* complex and are not therefore recognized by antibodies specific for other mycobacterial proteins.

10           The invention relates, in addition, to hybrid polypeptides having at least one polypeptide according to the invention and a sequence of a polypeptide capable of inducing an immune response in humans or animals.

          Advantageously, the antigenic determinant is such  
15       that it is capable of inducing a humoral and/or cellular response.

          Such a determinant may comprise a polypeptide according to the invention, in glycosylated form, which is used to obtain immunogenic compositions capable of inducing  
20       the synthesis of antibodies directed against multiple epitopes. Said glycosylated polypeptides also form part of the invention.

          These hybrid molecules may consist in part of a polypeptide-carrying molecule according to the invention  
25       combined with a portion, in particular an epitope of the diphtheria toxin, the tetanus toxin, a hepatitis B virus surface antigen (patent FR 79 21811), the VP1 antigen of the poliomyelitis virus or any other viral or bacterial toxin or antigen.

30           Advantageously, said antigenic determinant corresponds to an antigenic determinant of immunogenic

proteins of 45/47 kD of *M. tuberculosis* (international application PCT/FR 96/0166), or alternatively which are selected for example from ESAT6 (Harboe et al., 1996, Andersen et al., 1995, and Sorensen et al., 1995) and DES  
5 (PCT/FR 97/00923, Gicquel et al.).

A viral antigen, as defined above, will be preferably a hepatitis virus surface or envelope protein, for example the hepatitis B surface protein in one of its S, S-preS1, S-preS2 or S-preS2-preS1 forms or alternatively  
10 a protein of a hepatitis A virus, or of a hepatitis non-A, non-B virus, such as a hepatitis C, E or delta virus.

More particularly, a viral antigen as defined above will be the whole or part of one of the glycoproteins encoded by the genome of the HIV-1 virus (patents  
15 GB 8324800, EP 84401834 or EP 85905513) or of the HIV-2 virus (EP 87400151), and in particular the whole or part of a protein selected from gag, pol, nef or env of HIV-1 or HIV-2.

The methods for synthesizing the hybrid molecules  
20 include the methods used in genetic engineering to construct hybrid polynucleotides encoding the desired polypeptide sequences. Reference may be advantageously made, for example, to the technique for the production of genes encoding fusion proteins described by Minton in 1984.

25 Said hybrid polynucleotides encoding a hybrid polypeptide as well as the hybrid polypeptides according to the invention characterized in that they are recombinant proteins obtained by the expression of said hybrid polynucleotides also form part of the invention.

30 The polypeptides according to the invention may advantageously be used in a method for the *in vitro*

detection of antibodies directed against said polypeptides, in particular the polypeptide DP428, and also of antibodies directed against a bacterium of the *Mycobacterium tuberculosis* complex, in a biological sample (biological  
5 tissue or fluid) capable of containing them, this method comprising bringing this biological sample into contact with a polypeptide according to the invention under conditions allowing an immunological reaction *in vitro* between said polypeptide and the antibodies which may be  
10 present in the biological sample, and detecting *in vitro* the antigen-antibody complexes which may be formed.

The polypeptides according to the invention may also and advantageously be used in a method for the detection of an infection by a bacterium of the  
15 *Mycobacterium tuberculosis* complex in a mammal based on the *in vitro* detection of a cellular reaction indicating prior sensitization of the mammal to said polypeptide such as for example cell proliferation, the synthesis of proteins such as interferon-gamma. This method for the detection of an  
20 infection by a bacterium of the *Mycobacterium tuberculosis* complex in a mammal is characterized in that it comprises the following steps:

- a) preparation of a biological sample containing cells of said mammal, more particularly cells of the immune system  
25 of said mammal and still more particularly T cells;
- b) incubation of the biological sample of step a) with a polypeptide according to the invention;
- c) detection of a cellular reaction indicating prior sensitization of the mammal to said polypeptide such as for  
30 example cell proliferation and/or the synthesis of proteins such as interferon-gamma.

Cell proliferation may be measured, for example, by incorporation of  $^3\text{H}$ -Thymidine.

Also forming part of the invention are the methods for the detection of a delayed hypersensitivity  
5 reaction (DTH), characterized in that they use a polypeptide according to the invention.

Preferably, the biological sample consists of a fluid, for example a human or animal serum, blood, biopsies, bronchoalveolar fluid or pleural fluid.

10 Any conventional procedure may be used to carry out such a detection.

By way of example, a preferred method uses immunoenzymatic procedures such as the ELISA, immuno-fluorescence or radioimmunoassay (RIA) technique and the  
15 like.

Thus, the invention also relates to the polypeptides according to the invention, labeled with the aid of a suitable marker of the enzymatic, fluorescent or radioactive type.

20 Such methods comprise, for example, the following steps:

- deposition of predetermined quantities of a polypeptide composition according to the invention into the wells of a microtiter plate,
- 25 - introduction into said wells of increasing dilutions of serum or of another biological sample as defined above, before being analyzed,
- incubation of the microplate,
- introduction into the wells of the microtiter plate of  
30 labeled antibodies directed against human or animal immunoglobulins, the labeling of these antibodies having

been carried out with the aid of an enzyme selected from those which are capable of hydrolyzing a substrate while modifying its radiation absorption, at least at a defined wavelength, for example at 550 nm,

- 5 - detection, by comparing with a control, of the quantity of substrate hydrolyzed.

The invention also relates to a box or kit for the *in vitro* diagnosis of an infection by a mycobacterium belonging to the *Mycobacterium tuberculosis* complex,  
10 comprising:

- a polypeptide according to the invention,
- where appropriate, the reagents for constituting the medium which is appropriate for the immunological or specific reaction,
- 15 - the reagents allowing the detection of the antigen-antibody complexes produced by the immunological reaction which may be present in the biological sample, and the *in vitro* detection of the antigen-antibody complexes which may be formed, it being possible for these reagents to also  
20 carry a marker, or to be capable of being recognized in turn by a labeled reagent, more particularly in the case where the polypeptide according to the invention is not labeled,
- where appropriate, a reference biological sample  
25 (negative control) free of antibodies recognized by a polypeptide according to the invention,
- where appropriate, a reference biological sample (positive control) containing a predetermined quantity of antibodies recognized by a polypeptide according to the  
30 invention.

The polypeptides according to the invention make it possible to prepare monoclonal or polyclonal antibodies which are characterized in that they recognize specifically the polypeptides according to the invention. The monoclonal antibodies may be advantageously prepared from hybridomas according to the technique described by Kohler and Milstein in 1975. The polyclonal antibodies may be prepared, for example, by immunizing an animal, in particular a mouse, with a polypeptide according to the invention combined with an immune response adjuvant, and then purifying the specific antibodies contained in the serum of the immunized animals on an affinity column to which the polypeptide which served as antigen has been attached beforehand. The polyclonal antibodies according to the invention may also be prepared by purifying an affinity column, to which there have been immobilized beforehand a polypeptide according to the invention, antibodies contained in the serum of patients infected with a mycobacterium and preferably a bacterium belonging to the *Mycobacterium tuberculosis* complex.

The subject of the invention is also mono- or polyclonal antibodies or fragments thereof, or chimeric antibodies, characterized in that they are capable of recognizing specifically a polypeptide according to the invention.

The antibodies of the invention may also be labeled in the same manner as described above for the nucleic probes of the invention, such as a labeling of the enzymatic, fluorescent or radioactive type.

The invention relates, in addition, to a method for the specific detection of the presence of an antigen of

a mycobacterium and preferably a bacterium of the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following steps:

- 5 a) bringing the biological sample (biological tissue or fluid) collected from an individual into contact with a mono- or polyclonal antibody according to the invention, under conditions allowing an immunological reaction *in vitro* between said antibodies and the polypeptides specific to mycobacteria and preferably bacteria of the *Mycobacterium tuberculosis* complex which may be present in the biological sample, and
- 10 b) detection of the antigen-antibody complex formed.

Also coming within the scope of the invention is a box or kit for the *in vitro* diagnosis, on a biological sample, of the presence of strains of mycobacteria and preferably of bacteria belonging to the *Mycobacterium tuberculosis* complex, preferably *M. tuberculosis*, characterized in that it comprises:

- a polyclonal or monoclonal antibody according to the invention, labeled where appropriate;
- 20 - where appropriate, a reagent for constituting the medium which is appropriate for carrying out the immunological reaction;
- a reagent allowing the detection of the antigen-antibody complexes produced by the immunological reaction, it being possible for this reagent to also carry a marker, or to be capable of being recognized in turn by a labeled reagent, more particularly in the case where said monoclonal or polyclonal antibody is not labeled;
- 25 - where appropriate, reagents for carrying out the lysis of the cells of the sample tested.
- 30

The subject of the present invention is also a method for the detection and rapid identification of the mycobacteria and preferably of the *M. tuberculosis* bacteria in a biological sample, characterized in that it comprises  
5 the following steps:

- a) isolation of the DNA from the biological sample to be analyzed, or production of a cDNA from the RNA of the biological sample;
- b) specific amplification of the DNA of mycobacteria and  
10 preferably of bacteria belonging to the *Mycobacterium tuberculosis* complex with the aid of primers according to the invention;
- c) analysis of the products of amplification.

The products of amplification may be analyzed by  
15 various methods.

Two methods of analysis are given by way of example below:

- agarose gel electrophoretic analysis of the products of amplification. The presence of a DNA fragment  
20 which migrates to the expected position suggests that the sample analyzed contained DNA of mycobacteria belonging to the tuberculosis complex, or

- analysis by the molecular hybridization technique using a nucleic probe according to the invention.  
25 This probe will be advantageously labeled with a nonradioactive (cold probe) or radioactive element.

For the purposes of the present invention, "DNA of the biological sample" or "DNA contained in the biological sample" is understood to mean either the DNA  
30 present in the biological sample considered, or the cDNA

obtained after the action of a reverse transcriptase-type enzyme on the RNA present in said biological sample.

Another method of the present invention allows the detection of an infection by a mycobacterium and preferably a bacterium of the *Mycobacterium tuberculosis* complex in a mammal. This method comprises the following steps:

- a) preparation of a biological sample containing cells of said mammal, more particularly cells of the immune system of said mammal and still more particularly T cells;
- b) incubation of the biological sample of step a) with a polypeptide according to the invention;
- c) detection of a cellular reaction indicating prior sensitization of the mammal to said polypeptide in particular cell proliferation and/or the synthesis of proteins such as interferon-gamma;
- d) detection of a reaction of delayed hypersensitivity or of sensitization of the mammal to said polypeptide.

This method of detection is an intradermal method which is described for example by M.J. Elhay et al. (1988) *Infection and Immunity*, 66(7): 3454-3456.

Another aim of the present invention consists in a method for the detection of the mycobacteria and preferably the bacteria belonging to the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following steps:

- a) bringing an oligonucleotide probe according to the invention into contact with a biological sample, the DNA contained in the biological sample, or the cDNA obtained by reverse transcription of the RNA of the biological sample, having, where appropriate, been made accessible to the

hybridization beforehand, under conditions allowing the hybridization of the probe with the DNA or the cDNA of the mycobacteria and preferably of the bacteria of the *Mycobacterium tuberculosis* complex;

- 5 b) detection of the hybrid formed between the oligonucleotide probe and the DNA of the biological sample.

The invention also relates to a method for the detection of the mycobacteria and preferably of the bacteria belonging to the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following steps:

- 10 a) bringing an oligonucleotide probe according to the invention, immobilized on a support, into contact with a biological sample, the DNA of the biological sample having, where appropriate, been made accessible to the hybridization beforehand, under conditions allowing the hybridization of said probe with the DNA of the mycobacteria and preferably of the bacteria of the *Mycobacterium tuberculosis* complex;
- 15 b) bringing the hybrid formed between said oligonucleotide probe immobilized on a support and the DNA contained in the biological sample, where appropriate after removal of the DNA of the biological sample which has not hybridized with the probe, into contact with a labeled oligonucleotide probe according to the invention.

According to an advantageous embodiment of the method of detection defined above, it is characterized in that, prior to step a), the DNA of the biological sample is amplified beforehand with the aid of a pair of primers according to the invention.

Another embodiment of the method of detection according to the invention consists in a method for the detection of the presence of the mycobacteria and preferably the bacteria belonging to the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following steps:

- a) bringing the biological sample into contact with a pair of primers according to the invention, the DNA contained in the sample having been, where appropriate, made accessible to hybridization beforehand, under conditions allowing hybridization of said primers with the DNA of the mycobacteria and preferably of the bacteria of the *Mycobacterium tuberculosis* complex;
- b) amplification of the DNA of a mycobacterium and preferably of a bacterium of the *Mycobacterium tuberculosis* complex;
- c) detection of the amplification of the DNA fragments corresponding to the fragment flanked by the primers, for example by gel electrophoresis or by means of an oligonucleotide probe according to the invention.

A subject of the invention is also a method for the detection of the presence of the mycobacteria and preferably the bacteria belonging to the *Mycobacterium tuberculosis* complex in a biological sample by strand displacement, characterized in that it comprises the following steps:

- a) bringing the biological sample into contact with two pairs of primers according to the invention specifically intended for amplification of the SDA type described above, the DNA content in the sample having been, where appropriate, made accessible to hybridization beforehand,

under conditions allowing hybridization of the primers with the DNA of the mycobacteria and preferably the bacteria of the *Mycobacterium tuberculosis* complex;

5 b) amplification of the DNA of the mycobacteria and preferably of the bacteria of the *Mycobacterium tuberculosis* complex;

10 c) detection of the amplification of DNA fragments corresponding to the fragment flanked by the primers, for example by gel electrophoresis or by means of an oligonucleotide probe according to the invention.

The invention also relates to a box or kit for carrying out the method described above, intended for the detection of the presence of the mycobacteria and preferably the bacteria of the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following components:

a) an oligonucleotide probe according to the invention;

b) the reagents necessary for carrying out a hybridization reaction;

20 c) where appropriate, a pair of primers according to the invention as well as the reagents necessary for a reaction of amplification of the DNA (genomic DNA, plasmid DNA or cDNA) of mycobacteria and preferably of bacteria of the *Mycobacterium tuberculosis* complex.

25 The subject of the invention is also a kit or box for the detection of the presence of the mycobacteria and preferably the bacteria of the *Mycobacterium tuberculosis* complex in a biological sample, characterized in that it comprises the following components:

30 a) an oligonucleotide probe, termed capture probe, according to the invention;

- b) an oligonucleotide probe, termed revealing probe, according to the invention;
- c) where appropriate, a pair of primers according to the invention as well as the reagents necessary for a reaction
- 5 of amplification of the DNA of mycobacteria and preferably of bacteria of the *Mycobacterium tuberculosis* complex.

The invention also relates to a kit or box for the amplification of the DNA of the mycobacteria and preferably the bacteria of the *Mycobacterium tuberculosis*

10 complex present in a biological sample, characterized in that it comprises the following components:

- a) a pair of primers according to the invention;
- b) the reagents necessary for carrying out a DNA amplification reaction;
- 15 c) optionally, a component which makes it possible to verify the sequence of the amplified fragment, more particularly an oligonucleotide probe according to the invention.

Another subject of the present invention relates

20 to an immunogenic composition, characterized in that it comprises a polypeptide according to the invention.

Another immunogenic composition according to the invention is characterized in that it comprises one or more polypeptides according to the invention and/or one or more

25 hybrid polypeptides according to the invention.

According to an advantageous embodiment, the above-defined immunogenic composition constitutes a vaccine when it is provided in combination with a pharmaceutically acceptable vehicle and optionally one or more immunity

30 adjuvants such as alum or a representative of the family of

muramyl peptides or alternatively incomplete Freund's adjuvant.

- Various types of vaccine are currently available for protecting humans against infectious diseases:
- 5 attenuated live microorganisms (*M. bovis* - BCG for tuberculosis), inactivated microorganisms (influenza virus), acellular extracts (*Bordetella pertussis* for whooping cough), recombinant proteins (hepatitis B virus surface antigen), polysaccharides (pneumococci).
  - 10 Experiments are being carried out on vaccines prepared from synthetic peptides or genetically modified microorganisms expressing heterologous antigens. More recently still, recombinant plasmid DNAs carrying genes encoding protective antigens have been proposed as an alternative vaccine
  - 15 strategy. This type of vaccination is carried out with a specific plasmid which is derived from an *E. coli* plasmid which does not replicate *in vivo* and which encodes only the vaccinal protein. The principal functional components of this plasmid are: a strong promoter allowing expression in
  - 20 eukaryotic cells (for example that of CMV), an appropriate cloning site for inserting the gene of interest, a termination-polyadenylation sequence, a prokaryotic replication origin for producing the recombinant plasmid *in vitro* and a selectable marker (for example the
  - 25 ampicillin-resistance gene) for facilitating the selection of the bacteria which contain the plasmid. Animals were immunized by simply injecting the naked plasmid DNA into the muscle. This technique leads to the expression of the vaccinal protein *in situ* and to an immune response in
  - 30 particular of the cellular type (CTL) and of the humoral type (antibody). This double induction of the immune

response is one of the main advantages of the vaccination technique with naked DNA. Huygen et al. (1996) and Tascon et al. (1996) succeeded in obtaining a degree of protection against *M. tuberculosis* by injecting recombinant  
5 plasmids containing *M. leprae* genes (*hsp65*, *36kDa pra*) as inserts. *M. leprae* is the agent responsible for leprosy. The use of an insert specific to *M. tuberculosis* such as, for example, the whole or part of the *DP428* gene, which is the subject of the present invention, would probably lead  
10 to a better protection against tuberculosis. The whole or part of the *DP428* gene, or any polynucleotide according to the invention, can be easily inserted into the plasmid vectors V1J (Montgomery et al., 1993), pcDNA3 (Invitrogen, R & D Systems) or pcDNA1/Neo (Invitrogen) which possess the  
15 necessary characteristics for a vaccinal use.

The invention thus relates to a vaccine, characterized in that it comprises one or more polypeptides according to the invention and/or one or more hybrid polypeptides according to the invention as previously  
20 defined, in combination with a pharmaceutically compatible vehicle and, where appropriate, one or more appropriate immunity adjuvants.

The invention also relates to a vaccine composition intended for the immunization of humans or  
25 animals against a bacterial or viral infection, such as tuberculosis or hepatitis, characterized in that it comprises one or more hybrid polypeptides as previously defined in combination with a pharmaceutically compatible vehicle and, where appropriate, one or more immunity  
30 adjuvants.

Advantageously, in the case of a protein which is a hybrid between a polypeptide according to the invention and the hepatitis B surface antigen, the vaccine composition will be administered, in humans, in an amount  
5 of 0.1 to 1  $\mu\text{g}$  of purified hybrid protein per kilogram of the weight of the patient, preferably 0.2 to 0.5  $\mu\text{g}/\text{kg}$  of the weight of the patient, for a dose intended for a given administration. In the case of patients suffering from disorders of the immune system, in particular  
10 immunosuppressed patients, each injected dose will preferably contain half of the quantity, by weight, of the hybrid protein contained in a dose intended for a patient not suffering from immune system disorders.

Preferably, the vaccine composition will be  
15 administered several times, spread out over time, by the intradermal or subcutaneous route. By way of example, three doses as defined above will be administered, respectively, to the patient at time  $t_0$ , at time  $t_0 + 1$  month and at time  $t_0 + 1$  year.

20 Alternatively, three doses will be administered, respectively, to the patient at time  $t_0$ , at time  $t_0 + 1$  month and at time  $t_0 + 6$  months.

In mice, in which a weight dose of the vaccine composition comparable to the dose used in humans is  
25 administered, the antibody reaction is tested by collecting serum followed by a study of the formation of a complex between the antibodies present in the serum and the antigen of the vaccine composition, according to the customary techniques.

30 The invention also relates to an immunogenic composition characterized in that it comprises a

polynucleotide or an expression vector according to the invention, in combination with a vehicle allowing its administration to humans or animals.

5 The subject of the invention is also a vaccine intended for immunizing against a bacterial or viral infection, such as tuberculosis or hepatitis, characterized in that it comprises a polynucleotide or an expression vector according to the invention, in combination with a pharmaceutically acceptable vehicle.

10 Such immunogenic or vaccine compositions are in particular described in international application No. WO 90/11092 (Vical Inc.) and also in international application No. WO 95/11307 (Institut Pasteur).

15 The constituent polynucleotide of the immunogenic composition or of the vaccine composition according to the invention may be injected into the host after having been coupled with compounds which promote the penetration of this polynucleotide into the cell or its transport to the cell nucleus. The resulting conjugates may be encapsulated  
20 into polymer microparticles, as described in international application No. WO 94/27238 (Medisorb Technologies International).

According to another embodiment of the immunogenic and/or vaccine composition according to the  
25 invention, the polynucleotide, preferably a DNA, is complexed with DEAE-dextran (Pagano et al., 1967) or with nuclear proteins (Kaneda et al., 1989), with lipids (Felgner et al., (1987) or encapsulated into liposomes (Fraley et al., 1980).

30 According to yet another advantageous embodiment of the immunogenic and/or vaccine composition according to

the invention, the polynucleotide according to the invention may be introduced in the form of a gel facilitating its transfection into cells. Such a composition in gel form may be a poly-L-lysine and lactose  
5 complex, as described by Midoux in 1993, or Poloxamer 407<sup>TM</sup>, as described by Pastore in 1994. The polynucleotide or the vector according to the invention may also be in suspension in a buffer solution or may be combined with liposomes.

Advantageously, such a vaccine will be prepared  
10 in accordance with the technique described by Tacson et al. or Huygen et al. in 1996 or in accordance with the technique described by Davis et al. in international application No. WO 95/11307 (Whalen et al.).

Such a vaccine will be advantageously prepared in  
15 the form of a composition containing a vector according to the invention, placed under the control of regulatory elements allowing its expression in humans or animals.

To produce such a vaccine, the polynucleotide according to the invention is first of all subcloned into  
20 an appropriate expression vector, particularly an expression vector containing regulatory and expression signals recognized by the enzymes in eukaryotic cells and also containing a replication origin which is active in prokaryotes, for example in *E. coli*, which allows its prior  
25 amplification. The purified recombinant plasmid obtained is then injected into the host, for example by the intramuscular route.

It will be possible, for example, to use as vector for expressing *in vivo* the antigen of interest the  
30 plasmid pcDNA3 or the plasmid pcDNA1/neo, both marketed by Invitrogen (R&D Systems, Abingdon, United Kingdom). It is

also possible to use the plasmid V1Jns.tPA described by Shiver et al. in 1995.

Such a vaccine will advantageously comprise, in addition to the recombinant vector, a saline solution, for example a sodium chloride solution.

A vaccine composition as defined above will be, for example, administered by the parenteral route or by the intramuscular route.

The present invention also relates to a vaccine characterized in that it contains one or more nucleotide sequences according to the invention and/or one or more polynucleotides as mentioned above in combination with a pharmaceutically compatible vehicle and, where appropriate, one or more appropriate immunity adjuvants.

Another aspect relates to a method of screening molecules capable of inhibiting the growth of mycobacteria or the maintenance of mycobacteria in a host, characterized in that said molecules block the synthesis or the function of the polypeptides encoded by a nucleotide sequence according to the invention or by a polynucleotide as described supra.

In said method of screening, the molecules may be anti-messengers or may induce the synthesis of anti-messengers.

The present invention also relates to molecules capable of inhibiting the growth of mycobacteria or the maintenance of mycobacteria in a host, characterized in that said molecules are synthesized based on the structure of the polypeptides encoded by a nucleotide sequence according to the invention or by a polynucleotide as described supra.

Other characteristics and advantages of the invention appear in the following examples and figures:

## FIGURES

5

The Figure 1 series:

The Figure 1 series illustrates the series of nucleotide sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and  
10 33 corresponding to the insert of the vector pDP428 (deposited at the CNCM under the No. I-1818) and the series of amino acid sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 2-7, 9-13, 15-24, 26-30, 32, and 34 of the polypeptides encoded by the series of nucleotide sequences ~~SEQ ID No. 1~~  
15 SEQ ID NOS: 1, 8, 14, 25, 31, and 33.

Figure 2:

Illustrates the nucleotide sequence ~~SEQ ID No. 1~~  
20 SEQ ID NO: 35 corresponding to the region including the gene encoding the polypeptide DP428 (region underlined). Both the ATG and GTG codons for initiation of translation were taken into account in this figure. The figure shows that the polypeptide DP428 is probably part of an operon  
25 comprising at least three genes. The double-boxed region probably includes the promoter regions.

The single-boxed region corresponds to the motif LPISG (SEQ ID NO: 934) which resembles the motif LPXTG (SEQ ID NO: 935) described in Gram-positive bacteria as allowing  
30 anchorage to peptidoglycans.

The Figure 3 series:

5 The Figure 3 series represents the series of nucleotide sequences ~~SEQ ID No. 3~~ SEQ ID NOS: 41, 46, and 52 corresponding to the insert of the vector p6D7 (deposited at the CNCM under the No. I-1814) and the series of amino acid sequences SEQ ID NOS: 42-45, 47-51, and 53-55.

10 The Figure 4 series:

The Figure 4 series represents the series of nucleotide sequences ~~SEQ ID No. 4~~ SEQ ID NOS: 56, 62, 64, 67, 69, 72, 74, 76, 78, 81, 84, and 86 corresponding to the insert of  
15 the vector p5A3 (deposited at the CNCM under the No. I-1815) and the series of amino acid sequences SEQ ID NOS: 57-61, 63, 65-66, 68, 70-71, 73, 75, 77, 79-80, 81-83, 85, 87.

20 The Figure 5 series:

The Figure 5 series represents the series of nucleotide sequences ~~SEQ ID No. 5~~ SEQ ID NOS: 88, 90, 92, 96, 98, 100, 104, 106, and 108 corresponding to the insert of the  
25 vector p5F6 (deposited at the CNCM under the No. I-1816) and the series of amino acid sequences SEQ ID NOS: 93-95, 97, 99, 101-103, 105, 107, and 109.

The Figure 6 series:

30

The Figure 6 series represents the series of nucleotide sequences ~~SEQ ID No. 6~~ SEQ ID NOS: 110, 113, and 119 corresponding to the insert of the vector p2A29 (deposited at the CNCM under the No. I-1817) and the series of amino  
5 acid sequences SEQ ID NOS: 111-112, 114-118, and 120-121.

The Figure 7 series:

The Figure 7 series represents the series of nucleotide  
10 sequences ~~SEQ ID No. 7~~ SEQ ID NOS: 122, 128, and 133 corresponding to the insert of the vector p5B5 (deposited at the CNCM under the No. I-1819) and the series of amino  
acid sequences SEQ ID NOS: 123-127, 129-132, and 134-136.

15 The Figure 8 series:

The Figure 8 series represents the series of nucleotide sequences ~~SEQ ID No. 8~~ SEQ ID NOS: 137, 139, 141, 143, 145, 148, 150, 152, 154, and 156 corresponding to the  
20 insert of the vector p1C7 (deposited at the CNCM under the No. I-1820) and the series of amino acid sequences SEQ ID  
NOS: 138, 272-273, 140, 142, 144, 146-147, 149, 151, 153, 155, and 157.

25 The Figure 9 series:

The Figure 9 series represents the series of nucleotide sequences ~~SEQ ID No. 9~~ SEQ ID NOS: 158, 160, and 162 corresponding to the insert of the vector p2D7 (deposited  
30 at the CNCM under the No. I-1821) and the series of amino  
acid sequences SEQ ID NOS: 159, 161, and 163.

The Figure 10 series:

5 The Figure 10 series represents the series of nucleotide sequences ~~SEQ ID No. 10~~ SEQ ID NOS: 165, 169, and 177 corresponding to the insert of the vector p1B7 (deposited at the CNM under the No. I-1843) and the series of amino acid sequences SEQ ID NOS: 166-168, 170-176, and 178-183.

10 The Figure 11 series:

The Figure 11 series represents the series of nucleotide sequences ~~SEQ ID No. 11~~ SEQ ID NOS: 184, 189, 195, 200, 202, 206, 209, and 211 and the series of amino acid sequences SEQ ID NOS: 185-188, 190-194, 196-199, 201, 203-205, 207-208, 210, and 212.

15

The Figure 12 series:

20 The Figure 12 series represents the series of nucleotide sequences ~~SEQ ID No. 12~~ SEQ ID NOS: 213, 217, and 220 and the series of amino acid sequences SEQ ID NOS: 214-216, 218-219, and 221-224.

25 The Figure 13 series:

The Figure 13 series represents the series of nucleotide sequences ~~SEQ ID No. 13~~ SEQ ID NOS: 225, 228, 238, 246, 250, 255, 258, and 260 and the series of amino acid sequences SEQ ID NOS: 226-227, 229-237, 239-245, 247-249, 251-254, 256-257, 259, and 261.

30

The Figure 14 series:

5 The Figure 14 series represents the series of nucleotide  
sequences SEQ ID No. 14 SEQ ID NOS: 262, 268, 274, 278,  
280, 282, 284, 286, 288, 297, 290, and 310 corresponding to  
the insert of the vector p5B5 (deposited at the CNCM under  
the No. I-1819) and the series of amino acid sequences SEQ  
ID NOS: 263-267, 269-271, 275-277, 279, 281, 283, 285, 287,  
10 289, 291-296, 298-309, and 311-316.

The Figure 15 series:

15 The Figure 15 series represents the series of nucleotide  
sequences SEQ ID No. 15 SEQ ID NOS: 317, 321, 323, 325,  
327, 331, 333, 335, 337, 339, 346, and 347 and the series  
of amino acid sequences SEQ ID NOS: 318-320, 322, 324, 326,  
328-330, 332, 334, 336, 338, 340-345, and 348-352.

20 The Figure 16 series:

The Figure 16 series represents the series of nucleotide  
sequences SEQ ID No. 16 SEQ ID NOS: 353, 357, and 359 and  
the series of amino acid sequences SEQ ID NOS: 354-356,  
25 358, 360, and 926-930.

The Figure 17 series:

30 The Figure 17 series represents the series of nucleotide  
sequences SEQ ID No. 17 SEQ ID NOS: 361, 364, 368, 371,  
374, 380, 383, and 385 and the series of amino acid

sequences SEQ ID NOS: 362, 365-367, 369-370, 372, 373, 375-379, 381-382, 384, and 386.

The Figure 18 series:

20 The band which is most predominantly present in the lanes corresponding to the bacteria induced with IPTG compared with those not induced with IPTG, between 34,200 and 28,400 daltons, corresponds to the expression of the insert M1C25 cloned into the vector pQE-60 (Qiagen®).

25 As regards the legend to the other figures which are numbered by an alphanumeric character, each of these other figures represents the nucleotide sequence and the amino acid sequence having the SEQ ID sequence whose numbering is identical to the alphanumeric character of each of said figures.

The alphanumeric numberings of the figures representing the SEQ IDs comprising a number followed by a letter have the following meanings:

- 5     - the alphanumeric numberings having the same number relate to the same family of sequences attached to the reference SEQ ID sequence whose numbering has this same number and the letter A;
- 10    - the letters A, B and C for the same family of sequences distinguish the three possible reading frames of the reference SEQ ID nucleotide sequence (A);
- the letters with a prime (') index mean that the sequence corresponds to a fragment of the reference SEQ ID sequence (A);
- 15    - the letter D means that the sequence corresponds to the sequence of the gene predicted by Cole et al., 1998;
- the letter F means that the sequence corresponds to the open reading frame (ORF) containing the corresponding "D" sequence according to Cole et al., 1998;
- 20    - the letter G means that the sequence is a sequence predicted by Cole et al., 1998, and exhibiting a homology of more than 70% with the reference SEQ ID sequence (A);
- the letter H means that the sequence corresponds to the open reading frame containing the corresponding "G" sequence according to Cole et al., 1998;
- 25    - the letter R means that the sequence corresponds to a sequence predicted by Cole et al., 1998, upstream of the corresponding "D" sequence and capable of being in phase with the sequence "D" because of possible sequencing errors;

- the letter P means that the sequence corresponds to the open reading phase containing the corresponding "R" sequence;
- the letter Q means that the sequence corresponds to a sequence containing the corresponding "F" and "P" sequences.

As regards the sequence family ~~SEQ ID No. 4~~ SEQ ID NOS: 56 -87, the preceding insert *phoA* contains two fragments which are noncontiguous on the genome, ~~SEQ ID 4J~~ and ~~SEQ ID 4A~~ SEQ ID NO: 76 and SEQ ID NO: 56, and which are therefore derived from a multiple cloning allowing the expression and export of *phoA*. These two noncontiguous fragments, the genes and the open reading frames containing them according to Cole et al., 1998, are important for the export of an antigenic polypeptide:

- the letters J, K and L distinguish the three possible reading frames of the corresponding nucleotide sequence "J";
- the letter M means that the sequence corresponds to the sequence predicted by Cole et al., 1998, and containing the sequence ~~SEQ ID 4J~~ SEQ ID NO: 77;
- the letter N means that the sequence corresponds to the open reading frame containing the sequence ~~SEQ ID 4M~~ SEQ ID NO: 84.

As regards the sequence family ~~SEQ ID 45~~ SEQ ID NOS: 771-810, the letter Z means that the sequence corresponds to the sequence of a cloned fragment fused with *phoA*.

Finally, as regards the sequence family ~~SEQ ID 41~~ SEQ ID NOS: 678-727, the letter S means that the sequence corresponds to a sequence predicted by Cole et al., 1998

and which may be in the same reading frame as the corresponding sequence "D", the letter T meaning that the corresponding sequence contains the corresponding sequences "F" and "S".

5

### EXAMPLES

#### Materials and methods

#### 10 Bacterial cultures, plasmids and culture media

*E. coli* was cultured on Luria-Bertani (LB) solid or liquid medium. *M. smegmatis* was cultured on Middlebrook 7H9 liquid medium (Difco) supplemented with albumin-dextrose (ADC), 0.2% glycerol and 0.05% Tween, or on solid L medium. 15 If necessary, the antibiotic kanamycin was added at a concentration of 20 µg/ml. The bacterial clones having a PhoA activity were detected on LB agar containing 5-bromo-4-chloro-3-indolyl phosphate (X-P, at 40 µg/ml).

20

#### Manipulation of DNA and sequencing

The manipulations of DNA and the Southern-blot analyses were carried out using the standard techniques 25 (Sambrook et al., 1989). The double-stranded DNA sequences were determined with a Taq Dye Deoxy Terminator Cycle sequencing kit (Applied Biosystems), in a System 9600 GeneAmp PCR (Perkin-Elmer), and after migration on a model 373 DNA analyzing system (Applied Biosystems).

30

#### Constructions of the plasmids

The plasmid pJVED<sub>a</sub> was constructed from pLA71, a transfer plasmid comprising the *phoA* gene which is truncated and placed in phase with *BlaF*. pLA71 was cleaved  
5 with the restriction enzymes *KpnI* and *NotI*, thus removing *phoA* without affecting the promoter of *BlaF*. The *luc* gene encoding the firefly luciferase was amplified from pGEM-*luc* and a ribosome-binding site was added. *phoA* was amplified from pJEM11. The amplified fragments were cleaved with *PstI*  
10 and ligated together. The oligodeoxynucleotides used are the following:

pPV.*luc*.Fw: 5'GACTGCTGCAGAAGGAGAAGATCCAAATGG3'  
(SEQ ID NO: 911)  
15 *luc*.Bw: 5'GACTAGCGGCCGCGAATTCGTCTGACCTCCGAGG3'  
(SEQ ID NO: 912)  
*pJEM.phoA*.Fw: 5'CCGCGGATCCGGATACGTAC3'  
(SEQ ID NO: 913)  
*phoA*.Bw: 5'GACTGCTGCAGTTTATTTTCAGCCCCAGAGCG3'  
20 (SEQ ID NO: 914)

The fragment thus obtained was reamplified using the oligonucleotides complementary to its ends, cleaved with *KpnI* and *NotI*, and integrated into pLA71 cleaved with the same enzymes. The resulting construct was  
25 electroporated into *E. coli* DH5 $\alpha$  and *M. smegmatis* mc<sup>2</sup> 155. An *M. smegmatis* clone emitting light and having a *phoA* activity was selected and called pJVED/*blaF*. The insert was removed using *BamHI* and the construct closed again on itself, thus reconstructing pJVED<sub>a</sub>. To obtain pJVED<sub>b,c</sub>, the  
30 multiple cloning site was cleaved with *ScaI* and *KpnI* and closed again, removing one (pJVED<sub>b</sub>) or two (pJVED<sub>c</sub>)

nucleotides from the *Sna*BI site. After fusion, it was thus possible to obtain six reading frames. The insert of pJVED/*hsp18* was obtained by polymerase chain amplification (PCR) of pPM1745 (Servant et al., 1995) using  
5 oligonucleotides having the sequence:

18.Fw: 5'GTACCAGTACTGATCACCCGTCTCCCGCAC3'

(SEQ ID NO; 915)

18.Back: AGTCAGGTACCTCGCGGAAGGGGTCTAGTGCG3'

(SEQ ID NO: 916)

10 The product was cleaved with *Kpn*I and *Sca*I, and ligated to pJVED<sub>a</sub>, cleaved with the same enzymes, thus leaving pJVED/*hsp18*.

pJVED/*P19kDa* and pJVED/*erp* were constructed by cleaving with *Bam*HI the insert of pExp410 and pExp53,  
15 respectively, and inserting them into the *Bam*HI site of the multiple cloning site of pJVED<sub>a</sub>.

#### Measurement of the alkaline phosphatase activity

20 The presence of activity is detected by the blue color of the colonies growing on a culture medium containing the substrate 5-bromo-4-chloro-3-indolyl phosphate (XP), and then the activity can be quantitatively measured more precisely in the following manner:

25 *M. smegmatis* was cultured in an LB medium supplemented with 0.05% Tween 80 (Aldrich) and kanamycin (20 µg/ml) at 37°C for 24 hours. The alkaline phosphatase activity was measured by the Brockman and Heppel method (Brockman et al., 1968) in a sonicated extract, with  
30 *p*-nitrophenyl phosphate as reaction substrate. The quantity of proteins was measured by the Bio-Rad assay. The alkaline

phosphatase activity is expressed as arbitrary units (optic density at 420 nm  $\times$   $\mu$ g of protein<sup>-1</sup>  $\times$  minutes<sup>-1</sup>).

#### Measurement of the luciferase activity

5

*M. smegmatis* was cultured in an LB medium supplemented with 0.05% Tween 80 (Aldrich) and kanamycin (20  $\mu$ g/ml) at 37°C for 24 hours and used in full exponential growth (OD at 600 nm between 0.3 and 0.8). The  
10 aliquots of bacterial suspensions were briefly sonicated and the cell extract was used to measure the luciferase activity. 25  $\mu$ l of the sonicated extract were mixed with 100  $\mu$ l of substrate (Promega luciferase assay system) automatically in a luminometer and the emitted light  
15 expressed in RLU (Relative Light Units). The bacteria were counted by serial dilutions of the origin suspension on LB-kanamycin agar medium and the luciferase activity expressed in RLU/ $\mu$ g of bacterial protein or in RLU/ $10^3$  bacteria.

20

Construction of *M. tuberculosis* and *M. bovis*-BCG genomic libraries

The libraries were obtained essentially using  
25 pJVED<sub>a,b,c</sub>, which are described above.

Preparation of macrophages derived from bone marrow and infection with recombinant *M. smegmatis*

30

The macrophages derived from bone marrow were prepared as described by Lang et al., 1991. In summary, the

bone marrow cells were removed from the femur of 6- to 12-week old C57BL/6 mice (Iffa-Credo, France). The cells in suspensions were washed and resuspended in DMEM enriched with 10% fetal calf serum, 10% of conditioned L-cell medium and 2 mM glutamine, without antibiotics.  $10^6$  cells were inoculated on flat-bottomed 24-well Costar plates in 1 ml. After four days at 37°C in a humid atmosphere containing a CO<sub>2</sub> content of 10%, the macrophages were rinsed and reincubated for an additional two to four days. The cells of a control well were lysed with triton x 100 at 0.1% in water and the nuclei enumerated. About  $5 \times 10^5$  adherent cells were counted. For the infection, *M. smegmatis* carrying the different plasmids was cultured in full exponential phase (OD<sub>600 nm</sub> between 0.4 and 0.8) and diluted to an OD of 0.1 and then 10-fold in a medium for macrophage. 1 ml was added to each well and the plates were centrifuged and incubated for four hours at 37°C. After three washes, the cells were incubated in a medium containing amikacin for two hours. After three new washes, the adherent infected cells were incubated in a macrophage medium overnight. The cells were then lysed in 0.5 ml of lysis buffer (Promega). 100 µl were sonicated and the light emitted was measured on 25 µm. Simultaneously, the bacteria were enumerated by spreading on L-agar-kanamycin (20 µg/ml). The light emitted is expressed in RLU/10<sup>3</sup> bacteria.

#### Analyses of the databanks

The nucleotide sequences were compared with EMBL and GenBank using the FASTA algorithm and the protein

sequences were analyzed by similitude by means of the PIR and Swiss Prot databanks using the BLAST algorithm.

**Example 1: The pJVED vectors**

5

The pJVED vectors (Figure 51) are plasmids carrying an *E. coli* truncated *phoA* gene without initiation codon, signal sequence and regulatory sequence. The multiple cloning site (MCS) allows the insertion of fragments of the genes encoding potential exported proteins as well as their regulatory sequences. Consequently, the fusion protein may be produced and may exhibit an alkaline phosphatase activity if it is exported. Only the fusions in phase may be produced. Thus, the MCS was modified so that the fusions may be obtained in six reading frames. The firefly luciferase *luc* gene was inserted downstream of *phoA*. The complete gene with the initiation codon, but without any promoter having been used, thus ought to be expressed with *phoA* as in a synthetic operon. A new ribosome-binding site was inserted eight nucleotides upstream of the *luc* initiation codon. Two transcriptional terminators are present in the pJVED vectors, one upstream of the MCS and a second downstream of *luc*. These vectors are *E. coli*-mycobacterium transfer plasmids with a kanamycin-resistance gene as selectable marker.

10

15

20

25

*phoA* and *luc* function as in an operon, but export is necessary for the *phoA* activity.

Four plasmids were constructed by insertion into the MCS of DNA fragments of diverse origin:

30

In the first construct called pJVED/*blaF*, the 1.4 kb fragment is derived from the plasmid already described pLA71 (Lim et al., 1995). This fragment, derived from the  $\beta$ -lactamase gene (*blaF*) of *M. fortuitum* D216  
5 (Timm et al., 1994), includes the hyperactive mutated promoter, the segment encoding 32 amino acids of the signal sequence and the first 5 amino acids of the mature protein. Thus, this construct includes the strongest promoter known in mycobacterium and the elements necessary for the export  
10 of the *phoA* fusion protein. Consequently, a strong light emission and a good *phoA* activity can be expected from this construct (cf. Figures 53 and 54).

Into a second construct called pJVED/*hsp18*, a 1.5 kb fragment was cloned from the plasmid already  
15 described pPM1745 (Servant et al., 1995). This fragment includes the nucleotides encoding the first ten amino acids of the 18 kb heat shock protein derived from *Streptomyces albus* (heat shock protein 18, HSP 18), the ribosome-binding site, the promoter and, upstream, regulatory sites  
20 controlling its expression. This protein belongs to the alpha-crystalline family of low-molecular weight HSP (Verbon et al., 1992). Its homolog, derived from *M. leprae*, the 18 kDa antigen, is already known to be induced during phagocytosis by a murine macrophage of the J-774 cell line  
25 (Dellagostinet et al., 1995). Under standard culture conditions, pJVED/*hsp18* shows a weak *luc* activity and no *phoA* activity (cf. Figures 53 and 54).

In a third construct, called pJVED/*P19kDa*, the insert derived from pExp410 (Lim et al., 1995) was cleaved  
30 and cloned into the MCS of pJVED<sub>a</sub>. This fragment includes the nucleotides encoding the first 134 amino acids of the

*M. tuberculosis* 19 kDa known protein and of its regulatory sequences. As has been demonstrated, this protein is a glycosylated lipoprotein (Garbe et al., 1993; Herrmann et al., 1996). In Figures 53 and 54, a good *luc* activity corresponding to a strong promoter is observed for this construct, but the *phoA* activity is the strongest of the four constructs. The high *phoA* activity of this fusion protein with a lipoprotein is explained by the fact that it remains attached to the cell wall by its N-terminal end.

10 In the fourth and last construct, called pJVED/*erp*, the insert is derived from pExp53 (Lim et al., 1995) and was cloned into the MCS of pJVED<sub>a</sub>. pExp53 is the initial plasmid selected for its *phoA* activity and containing a portion of the *M. tuberculosis* *erp* gene which encodes a  
15 28-kDa antigen. The latter includes the signal sequence, a portion of the mature protein and, upstream of the initiation codon, the ribosome-binding site. The promoter was mapped. A putative iron box of the *fur* type is present in this region and flanks the -35 region of the promoter  
20 (Berthet et al., 1995). As expected (Figures 53 and 54) this construct exhibits a good light emission and a good *phoA* activity. The fact that this fusion protein, unlike the fusion with the lipoprotein of 19 kDa, does not appear to be attached to the cell wall does not exclude that the  
25 native protein is combined with it. Furthermore, the C-terminal end of *erp* is absent from the fusion protein.

**Example 2:** Construction of an *M. tuberculosis* genomic DNA library in the pJVED<sub>s</sub> vectors and identification of one  
30 of the members of these libraries, (DP428), induced during phagocytosis by murine macrophages derived from bone marrow

The various constructs were tested for their capacity to evaluate the intracellular expression of the genes identified by the expression of *phoA*. For this purpose, the *luc* activity is expressed in RLU for 5  $10^3$  bacteria in axenic culture and/or under intracellular conditions. The induction or the repression following phagocytosis by the bone marrow-derived murine macrophages can be suitably evaluated by the measurement of specific activities. The results of two separate experiments are 10 presented in Table 2.

The plasmid pJVED/*hsp18* was used as positive control for the induction during the intracellular growth phase. Although the induction of the promoter by heating the bacterium at 42°C was not conclusive, the phagocytosis 15 of the bacterium clearly leads to an increase in the activity of the promoter. In all the experiments, the intracellular *luc* activity was strongly induced, increasing by 20 to 100-fold the initially weak basal activity (Servant, 1995).

20 The plasmid pJVED/*blaF* was used as a control for nonspecific modulation during the phagocytosis. It was possible to detect weak variations which were probably due to changes in culture conditions. Whatever the case, these weak variations are not comparable to the induction 25 observed with the plasmid pJVED/*hsp18*.

All the members of the DNA library were tested by measuring the activity of the promoter during the intracellular growth. Among these, DP428 is strongly induced during phagocytosis (Tables 1 and 2).

The nucleotide fragment encoding the N-terminal region of the polypeptide DP428 having the sequence ~~SEQ ID No. 28~~ SEQ ID NO: 543 is contained in the plasmid deposited

10 at the CNCM under the No. I-1818.

The entire sequence encoding the polypeptide DP428 was obtained as detailed below.

- A probe was obtained by PCR with the aid of oligonucleotides having the sequence ~~SEQ ID No. 25~~ and ~~SEQ ID No. 26~~ SEQ ID NO: 528 and SEQ ID NO: 529. This probe was labeled by random extension in the presence of [<sup>32</sup>P]dCTP.
- 5 Hybridization of the genomic DNA of *M. tuberculosis* strain Mt103 previously digested with the endonuclease *Sca*I was carried out with the aid of said probe. The results of the hybridization revealed that a DNA fragment of about 1.7 kb was labeled. Because an *Sca*I site exists, extending from
- 10 the nucleotide nt 984 to the nucleotide nt 989 of the sequences ~~SEQ ID No. 1~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33, that is to say on the 5' side of the sequence used as probe, the end of the coding sequence is necessarily present in the fragment detected by hybridization.
- 15 The genomic DNA of the *M. tuberculosis* Mt 103 strain, after digestion with *Sca*I, was subjected to migration on agarose gel. The fragments of between 1.6 and 1.8 kb in size were cloned into the vector pSL1180 (Pharmacia) previously cleaved with *Sca*I and
- 20 dephosphorylated. After transformation of *E. coli* with the resulting recombinant vectors, the colonies obtained were screened with the aid of the probe. The screening made it possible to isolate six colonies hybridizing with this probe.
- 25 The inserts contained in the plasmids of the previously selected recombinant clones were sequenced and then the sequences aligned so as to determine the entire sequence encoding DP428, more specifically ~~SEQ ID No. 2~~ SEQ ID NO: 35.
- 30 A pair of primers were synthesized in order to amplify, starting with the genomic DNA of *M. tuberculosis*,

strain Mt 103, the entire sequence encoding the polypeptide DP428. The amplicon obtained was cloned into an expression vector.

5 Pairs of primers appropriate for the amplification and the cloning of the sequence encoding the polypeptide DP428 can be easily produced by persons skilled in the art, on the basis of the nucleotide sequences ~~SEQ ID No. 1~~ and ~~SEQ ID No. 2~~ SEQ ID NOS: 1, 8, 14, 25, 31, and 33 and SEQ ID NO: 35.

10 A specific pair of primers according to the invention is the following pair of primers, which is capable of amplifying the DNA encoding the polypeptide DP428 lacking its signal sequence:

- forward primer ~~SEQ ID No. 29~~ (SEQ ID NO: 917),  
15 comprising the sequence going from the nucleotide at position nt ~~1021~~ 531 to the nucleotide nt ~~1044~~ 554 of the sequence ~~SEQ ID No. 2~~ SEQ ID NO: 35:

5' -AGTGCATGCTGCTGGCCGAACCATCAGCGAC- 3'

20 - backward primer ~~SEQ ID No. 30~~ (SEQ ID NO: 918), comprising the sequence complementary to the forward sequence of the nucleotide at position nt ~~1345~~ 855 to the nucleotide at position nt ~~1325~~ 835 of the sequence ~~SEQ ID No. 2~~ SEQ ID NO: 35:

25 5' -CAGCCAGATCTGCGGGCGCCCTGCACCGCCTG- 3',

in which the portion underlined represents the sequences hybridizing specifically with the sequence ~~SEQ ID No. 2~~ SEQ ID NO: 35 and the 5' ends correspond to restriction  
30 sites for the cloning of the resulting amplicon into a cloning and/or expression vector.

A specific vector used for the expression of the polypeptide DP428 is the vector pQE70 marketed by the company Qiagen.

5 **Example 3:** The complete sequence of the DP428 gene and its flanking regions

A probe of the coding region of DP428 was obtained by PCR and used to hybridize the genomic DNA of various  
10 mycobacterial species. According to the results of Figure 3, the gene is present only in mycobacteria of the *M. tuberculosis* complex.

Analysis of the sequence suggests that DP428 could be part of an operon. The coding sequence and the flanking  
15 regions exhibit no homology with known sequences deposited in databanks.

Based on the coding sequence, the gene encodes a 10 kDa protein with a signal peptide, a hydrophobic C-terminal end which ends with two arginines and is  
20 preceded by an LPISG (SEQ ID NO: 934) motif similar to the known LPXTG (SEQ ID NO: 935) motif. These two arginines could correspond to a retention signal and the protein DP428 could be attached via this motif to peptidoglycans as has already been described in other Gram<sup>+</sup> bacteria  
25 (Navarre et al., 1994 and 1996).

The mechanism for survival and intracellular growth of mycobacteria is complex and the intimate relationships between the bacteria and the host cell remain unexplained. Whatever the mechanism, the growth and the  
30 intracellular survival of mycobacteria depend on factors produced by the bacteria produced by the bacterium and

capable of modulating the response of the host. These factors may be molecules which are exposed at the cell surface, such as LAM or cell surface-associated proteins, or actively secreted molecules.

5           On the other hand, intracellularly, the bacteria themselves have to confront a hostile environment. They appear to respond to this by means similar to those used under stress conditions, by inducing heat shock proteins (Dellagostin et al., 1995), but also by the induction or  
10 the repression of various proteins (Lee et al., 1995). Using a methodology derived from PCR, Plum and Clark-urtiss (Plum et al., 1994) have shown that an *M. avium* gene included in a 3 kb DNA fragment is induced after phagocytosis by human macrophages. This gene encodes an  
15 exported protein comprising a leader sequence but exhibiting no significant homology with the sequences proposed by databanks. The induction, during the intracellular growth phase, of a low-molecular-weight heat shock protein derived from *M. leprae* has also been  
20 demonstrated (Dellagostin et al., 1995). In another study, the bacterial proteins from *M. tuberculosis* were metabolically labeled during the intracellular growth phase or under stress conditions and separated by two-dimensional gel electrophoresis: 16 *M. tuberculosis* proteins were  
25 induced and 28 were repressed. The same proteins are involved during stress caused by a low pH, a heat shock, H<sub>2</sub>O<sub>2</sub>, or during phagocytosis by human monocytes of the THP1 line. Whatever the case, the behavior of the induced and repressed proteins was unique under each condition (Lee et  
30 al., 1995). Taken together, these results indicate that a subtle molecular dialogue is installed between the bacteria

and their host cells. This dialogue probably depends on the fate of the intracellular organism.

In this context, the induction of the expression of DP428 could be of major importance, indicating an important role for this protein in intracellular survival and growth.

The method used in these experiments to evaluate the intracellular expression of the genes (cf. Jacobs et al., 1993, for the method for determining the expression of firefly luciferase, and Lim et al., 1995, for the method for determining the expression of the *PhoA* gene) has the advantage of being simple compared with the other techniques such as the technique described by Mahan et al. (Mahan et al., 1993) adapted to mycobacteria and proposed by Bange et al., (Bange et al., 1996) or the subtractive method based on PCR described by Plum and Clark-curtiss (Plum et al., 1994). Variability undoubtedly exists as shown by comparing the various experiments. Although causing the induction or the repression is sufficient, it is now possible to evaluate it, thus providing an additional tool for the physiological studies of the exported proteins identified by fusion with *phoA*.

**Example 4:**

Search for modulation of the activity of the promoters during the intramacrophage phases

Mouse bone marrow macrophages are prepared as described by Lang and Antoine (Lang et al., 1991). Recombinant *M. smegmatis* bacteria, whose luciferase activity per  $10^3$  bacteria has been determined as above, are

incubated at 37°C under a humid atmosphere enriched with 5% CO<sub>2</sub>, for 4 hours in the presence of these macrophages such that they are phagocytosed. After rinsing in order to remove the remaining extracellular bacteria, amikacin  
5 (100 µg/ml) is added to the culture medium for two hours. After another rinsing, the medium is replaced with an antibiotic-free culture medium (DMEM enriched with 10% calf serum and 2 mM glutamine). After overnight incubation as above, the macrophages are lysed at low temperature (4°C)  
10 with the aid of a lysis buffer (cee lysis buffer, Promega), and the luciferase activity per 10<sup>3</sup> bacteria is determined. The ratio of the activities at placing in culture and after one night gives the coefficient of induction.

15 **Example 5:**

Isolation of a series of sequences by sequencing directly using colonies

A series of sequences allowing the expression and  
20 export of *phoA* were isolated from the DNA of *M. tuberculosis* or of *M. bovis* BCG. Among this group of sequences, two of them were further studied, the entire genes corresponding to the inserts were cloned, sequenced and antibodies against the product of these genes served to  
25 show by electron microscopy that these genes encoded antigens found at the surface of the tubercle bacilli. One of these genes, *erp*, encoding a consensus export signal sequence, the other, *des*, possessed no characteristic of a gene encoding an exported protein, based on the sequence.  
30 Another gene, DP428, was sequenced before the sequence of the *M. tuberculosis* genome became available. It contains a

sequence resembling the consensus sequence for attachment to peptidoglycan, which suggests that it is also an antigen which is probably found at the surface of the tubercle bacilli. The study of the three genes, *erp*, *des*, and that  
5 encoding DP428, shows that the *phoA* system which we have developed in mycobacteria makes it possible to pick out genes encoding exported proteins with no determinant which can be picked out by studies *in silico*. This is particularly true for the polypeptides which do not possess  
10 a consensus signal sequence (*des*) or no similarity with proteins having a known function (*erp* and DP428).

A number of inserts were identified and sequenced before knowing the genome of *M. tuberculosis* or of others below. These sequences may be considered as primers which  
15 make it possible to search for genes encoding exported proteins. To date, a series of primers have been sequenced and the entire corresponding genes have been either sequenced or identified based on the published sequence of the genome. To take into account sequencing errors which  
20 are always possible, the regions upstream or downstream of some primers were considered as being capable of forming part of sequences encoding exported proteins. In some cases, similarities with genes encoding exported proteins or sequences characteristic of export signals or  
25 topological characteristics of membrane proteins were detected.

Primer sequences are found to correspond to genes belonging to families of genes possessing more than 50% similarity. It is thus possible to indicate that the other  
30 genes detected by similarity with a primer encode exported proteins. This is the case for the sequences ~~SEQ ID No. 86~~

and ~~SEQ ID No. 8H~~ SEQ ID NO: 154 and SEQ ID NO: 156 which possess more than 77% similarity with ~~SEQ ID No. 8A~~ the sequences SEQ ID NOS: 137 & 143.

The sequences which may encode exported proteins are the following: ~~SEQ ID No. 1, 8, 9, 8C, 8H, 13, 3, 10, 19, 20, 6, 16, 22, 23, 24, 39, 44, 46 and 50~~ SEQ ID NOS: 1, 8, 14, 25, 31, 33, 137, 139, 141, 143, 145, 148, 150, 152, 154, 156, 158, 160, 162, 225, 228, 238, 246, 250, 255, 258, 260, 41, 46, 52, 165, 169, 177, 407, 410, 412, 419, 421, 426, 429, 431, 433, 437, 441, 447, 452, 456, 459, 461, 110, 113, 119, 353, 357, 359, 489, 495, 497, 501, 505, 510, 516, 519, 522, 651, 653, 657, 660, 662, 759, 761, 764, 767, 769, 811, 813, 817, 821, 823, 887, 895, 901, 907, and 909.

Genes identified based on the primers from the sequence of the genome have no characteristic (based on the sequence) of the exported proteins. They are the following sequences: ~~SEQ ID No. 4, 27, 11, 12, 14, 7, 15, 17, 18, 21, 31, 32, 33, 34, 35, 36, 37, 38, 40, 41, 42, 43, 45, 47, 48 and 49~~ SEQ ID NOS: 57-61, 63, 65-66, 68, 70-71, 73, 75, 77, 79-80, 82-83, 85, 87, 531-533, 535-536, 538-542, 185-188, 190-194, 196-199, 201, 203-205, 207-208, 210, 212, 214-216, 218-219, 221-224, 263-267, 269-271, 275-277, 279, 281, 283, 285, 287, 289, 291-296, 298-309, 311-316, 123-127, 129-132, 134-136, 318-320, 322, 324, 326, 328-330, 332, 334, 336, 338, 340-345, 348-352, 362-363, 365-367, 369, 370, 372-373, 375-379, 381-382, 384, 386, 388, 390-392, 394, 396, 398, 400-402, 404, 406, 464-468, 470-471, 473, 475, 477-481, 483-484, 486, 488, 547-549, 551, 553, 555, 557, 559-563, 565-568, 570, 572, 574-575, 577-579, 581-583, 585, 587, 589, 591-593, 595, 597, 599, 601-603, 605-607, 609, 611, 613, 615, 617, 619, 621, 623, 625, 627-628, 630, 632, 634,

636-639, 641-646, 648, 650, 655, 931-933, 667-668, 670-673,  
675, 677, 679-682, 684-685, 687-690, 692, 694, 696, 698-  
701, 703-716, 718-727, 729-732, 734-735, 737, 738, 740,  
742, 744-745, 747-751, 753-754, 756, 758, 772-780, 781-783,  
5 785-793, 795-804, 806, 808, 810, 826, 828-830, 832, 834,  
836, 838, 840-841, 843, 845, 847, 849-863, 865-877, 879-  
882, 884, and 886.

Based on the sequence of other organisms such as  
*E.coli*, it is possible to search in the sequence of the *M.*  
10 *tuberculosis* genome for genes possessing similarities with  
proteins known to be exported in other organisms although  
not possessing an export signal sequence. In this case,  
fusion with *phoA* is an advantageous protocol for  
determining if these *M. tuberculosis* sequences encode  
15 exported proteins although possessing no consensus signal  
sequence. It has indeed been possible to clone ~~SEQ ID No.~~  
49 SEQ ID NOS: 848, 864, 878, 883, and 885, sequences  
similar to an *E.coli* gene of the *htrA* family. A fusion of  
~~SEQ ID No. 49~~ SEQ ID NOS: 848, 864, 878, 883, and 885 with  
20 *phoA* leads to the expression and the export of *phoA*. *M.*  
*smegmatis* colonies harboring ~~SEQ ID No. 49~~ SEQ ID NOS: 848,  
864, 878, 883, and 885 *phoA* fusion on a plasmid pJVED are  
blue.

~~SEQ ID No. 49~~ SEQ ID NOS: 849-863, 865-877, 879,  
25 880-882, 884, 886 are therefore considered ~~as an~~ exported  
proteins.

The *phoA* method is therefore useful for  
detecting, based on the *M. tuberculosis* sequence, genes  
encoding exported proteins without them encoding sequences  
30 which are characteristic of the exported proteins.

Even if a sequence possesses determinants of exported proteins, this does not demonstrate a functional export. The *phoA* system makes it possible to show that the gene suspected really encodes an exported protein. Thus, it

5 was checked that the sequences ~~SEQ ID No. 50~~ SEQ ID NOS: 887, 895, 901, 907, and 909 indeed possessed export signals.

Legend to Table 3:

Correspondence between the sequences according to the invention and the sequences predicted by Cole et al., 1998,

5 Nature, 393, 537-544.

\* : Prediction that the protein encoded by the sequence is exported

ML : Prediction of similarity with *M. leprae*.

10 **Example 6:**

Characteristics and production of the protein M1C25

The N-terminal end of the protein M1C25 was detected by the *PhoA* system as allowing the export of the fusion protein, necessary for the production of its phosphatase activity.

The DNA sequence encoding the N-terminal end of the protein M1C25 is contained in the sequences SEQ ID NOS: 433, 437, 441, 447, 452, 456, 459, 461 of the present patent application.

From this primer sequence, the complete gene encoding the protein M1C25 was sought in the *M. tuberculosis* genome (Wellcome Trust Foundation, Sanger site).

25 The Sanger center attributed to M1C25 the names:

Rv 3576,

MTCY06G11.23,

pknM

30 Sequence ~~SEQ ID No. 29~~ SEQ ID NO: 544 of the complete M1C25 gene (714 bases):

cf. Figure 29

This gene encodes a protein of 237 AA, having a molecular mass of 25 kDa. This protein is listed in the  
5 libraries under the names:

PID:e306716,

SPTREMBL:P96858

Sequence ~~SEQ ID No. 30~~ SEQ ID NO: 545 of the protein M1C25  
10 (237 amino acids): cf. Figure 30

M1C25 contains a site for attachment to the lipid portion of the prokaryotic membrane lipoproteins (PS00013 Prokaryotic membrane lipoprotein lipid attachment site:  
15 CTGGTCGGTG CGTGCATGCT CGCAGCCGGA TGC) (SEQ ID NO: 919).

The function of M1C25 is not clear but it most probably possesses a "serine/threonine protein kinase" activity. Similarities should be noted with the C-terminal moiety of K08G\_MYCTU Q11053 Rv1266c (MTCY50.16).  
20 Similarities are also found with KY28\_MYCTU.

A gene potentially encoding a regulatory protein (PID:e306715, SPTREMBL:P96857, Rv3575c, (MTCY06G11.22c)) is found in 5' of the gene encoding M1C25.

The hydrophobicity profile (Kyte and Doolittle) of  
25 M1C25 is represented in Figure 56.

A site of cleavage of the signal sequence is predicted (SignalP V1.1; World Wide Web Prediction Server, Center for Biological Sequence Analysis) between amino acids 31 and 32: AVA-AD. This cleavage site is behind a  
30 conventional "AXA" motif. This prediction is compatible with the hydrophobicity profile. In this potential signal

sequence, it is observed that the sequence of the three amino acids LAA is repeated three times.

Cloning of the M1C25 gene for the production of the protein  
5 which it encodes:

A pair of primers were synthesized in order to amplify, using the genomic DNA of *M. tuberculosis*, strain H37Rv, the entire sequence encoding the polypeptide M1C25.  
10 The amplicon obtained was cloned into an expression vector.

Pairs of primers appropriate for the amplification and the cloning of the sequence encoding M1C25 were synthesized:

- forward primer: (SEQ ID NO: 920)  
15 5'-ATAATACCATGGGCAAGCAGCTAGCCGCGC- 3'  
- backward primer: (SEQ ID NO: 921)  
5'-ATTTATAGATCTCTGCTTAGCAACCTTGGCCGCG- 3'

The underlined portion represents the sequences specifically hybridizing with the M1C25 sequence and the 5' ends correspond to restriction sites for the cloning of the  
20 resulting amplicon into a cloning and/or expression vector.

A specific vector used for the expression of the polypeptide M1C25 is the vector pQE60 marketed by the company Qiagen, following the protocol and the  
25 recommendations proposed by this brand.

The cells used for the cloning are bacteria: *E.coli* XL1-Blue (resistant to tetracycline).

The cells used for the expression are bacteria: *E.coli* M15 (resistant to kanamycin) containing the plasmid  
30 pRep4 (M15 pRep4).

The production of the protein MYC25 is illustrated by Figures 57 A and B (bacterial extracts from the *E.coli* M15 strain containing the plasmid pM1C25). The bacterial cultures and the extracts are prepared according to

5 Sambrook et al. (1989). Analysis of the bacterial extracts is carried out according to the Quiagen instructions (1997).
